Preface

These notes are designed to accompany 10 lectures on Denotational Semantics for Part II of the Cambridge University Computer Science Tripos. The aims of this course are to introduce domain theory and denotational semantics, and to show how they provide a mathematical basis for reasoning about the behaviour of programs.

Recommended books

- Winskel, G. (1993). *The Formal Semantics of Programming Languages*. MIT Press.

This is an excellent introduction to both the operational and denotational semantics of programming languages. As far as this course is concerned, the relevant chapters are 5, 8, 9, 10 (Sections 1 and 2), and 11.

- Tennent, R. D. (1991). *Semantics of Programming Languages*. Prentice-Hall.

Parts I and II are relevant to this course.

Further reading

- Gunter, C. A. (1992). *Semantics of Programming Languages. Structures and Techniques*. MIT Press.

This is a graduate-level text containing much material not covered in this course. As far as this course is concerned, the relevant chapters are 1, 2, and 4–6.

- Streicher, T. (2006). *Domain-Theoretic Foundations of Functional Programming*. World Scientific Publishing Co. ISBN 981-270-142-7

A graduate-level text about the PCF language covered in the second half of the course.

Andrew Pitts

Andrew.Pitts@cl.cam.ac.uk

1 Introduction

Slide 1 gives a reminder of various approaches to giving formal semantics for programming languages. The operational approach was introduced in the Part IB course on **Semantics of Programming Languages** and the axiomatic approach is illustrated in the Part II course on **Hoare Logic**. This course gives a brief introduction to some of the techniques of the denotational approach. One of the aims of Denotational Semantics is to specify programming language constructs in as abstract and implementation-independent way as possible: in this way one may gain insight into the fundamental concepts underlying programming languages, their inter-relationships, and (sometimes) new ways of realising those concepts in language designs. Of course, it is crucial to verify that denotational specifications of languages are implementable—in other words to relate denotational semantics to operational semantics: we will illustrate how this is done later in the course.

Styles of formal semantics

Operational.

Meanings for program phrases defined in terms of the *steps of computation* they can take during program execution.

Axiomatic.

Meanings for program phrases defined indirectly via the *axioms and rules* of some logic of program properties.

Denotational.

Concerned with giving *mathematical models* of programming languages. Meanings for program phrases defined abstractly as elements of some suitable mathematical structure.

Characteristic features of a denotational semantics

- Each phrase (= part of a program), P , is given a *denotation*, $\llbracket P \rrbracket$ — a mathematical object representing the contribution of P to the meaning of *any* complete program in which it occurs.
- The denotation of a phrase is determined just by the denotations of its subphrases (one says that the semantics is *compositional*).

Slide 2

1.1 Basic example of denotational semantics

Consider the basic programming language IMP^- over arithmetic and boolean expressions with control structures given by assignment, sequencing, and conditionals described on Slide 3.

Basic example of denotational semantics (I)

IMP⁻ syntax

Arithmetic expressions

$$A \in \mathbf{Aexp} ::= \underline{n} \mid L \mid A + A \mid \dots$$

where n ranges over *integers* and
 L over a specified set of *locations* \mathbb{L}

Boolean expressions

$$B \in \mathbf{Bexp} ::= \mathbf{true} \mid \mathbf{false} \mid A = A \mid \dots$$

$$\mid \neg B \mid \dots$$

Commands

$$C \in \mathbf{Comm} ::= \mathbf{skip} \mid L := A \mid C; C$$

$$\mid \mathbf{if } B \mathbf{ then } C \mathbf{ else } C$$

Slide 3

A *denotational semantics* for a programming language is constructed by giving a domain of interpretation to each of the program-phrase categories together with semantic functions that compositionally describe the meaning of the phrase-forming constructs. For IMP⁻ this is done in Slides 4–10, and is easily implementable in SML.

Basic example of denotational semantics (II)

Semantic functions

$$\mathcal{A} : \mathbf{Aexp} \rightarrow (State \rightarrow \mathbb{Z})$$

$$\mathcal{B} : \mathbf{Bexp} \rightarrow (State \rightarrow \mathbb{B})$$

$$\mathcal{C} : \mathbf{Comm} \rightarrow (State \rightarrow State)$$

where

$$\mathbb{Z} = \{ \dots, -1, 0, 1, \dots \}$$

$$\mathbb{B} = \{ true, false \}$$

$$State = (\mathbb{L} \rightarrow \mathbb{Z})$$

Slide 4

Basic example of denotational semantics (III)

Semantic function \mathcal{A}

$$\mathcal{A}[[n]] = \lambda s \in State. n$$

$$\mathcal{A}[[L]] = \lambda s \in State. s(L)$$

$$\mathcal{A}[[A_1 + A_2]] = \lambda s \in State. \mathcal{A}[[A_1]](s) + \mathcal{A}[[A_2]](s)$$

Slide 5

Basic example of denotational semantics (IV)

Semantic function \mathcal{B}

$$\mathcal{B}[\mathbf{true}] = \lambda s \in State. true$$

$$\mathcal{B}[\mathbf{false}] = \lambda s \in State. false$$

$$\mathcal{B}[A_1 = A_2] = \lambda s \in State. eq(\mathcal{A}[A_1](s), \mathcal{A}[A_2](s))$$

$$\text{where } eq(a, a') = \begin{cases} true & \text{if } a = a' \\ false & \text{if } a \neq a' \end{cases}$$

Slide 6**Basic example of denotational semantics (V)**

Semantic function \mathcal{C}

$$\llbracket \mathbf{skip} \rrbracket = \lambda s \in State. s$$

NB: From now on the names of semantic functions are omitted!**Slide 7**

A simple example of compositionality

Given partial functions $\llbracket C \rrbracket, \llbracket C' \rrbracket : State \rightarrow State$ and a function $\llbracket B \rrbracket : State \rightarrow \{true, false\}$, we can define

$$\llbracket \text{if } B \text{ then } C \text{ else } C' \rrbracket = \\ \lambda s \in State. \text{if} (\llbracket B \rrbracket(s), \llbracket C \rrbracket(s), \llbracket C' \rrbracket(s))$$

where

$$\text{if}(b, x, x') = \begin{cases} x & \text{if } b = true \\ x' & \text{if } b = false \end{cases}$$

Slide 8

Basic example of denotational semantics (VI)

Semantic function \mathcal{C}

$$\llbracket L := A \rrbracket = \\ \lambda s \in State. \lambda \ell \in \mathbb{L}. \text{if} (\ell = L, \llbracket A \rrbracket(s), s(\ell))$$

Slide 9

Denotational semantics of sequential composition

Denotation of sequential composition $C; C'$ of two commands

$$\llbracket C; C' \rrbracket = \llbracket C' \rrbracket \circ \llbracket C \rrbracket = \lambda s \in \text{State}. \llbracket C' \rrbracket(\llbracket C \rrbracket(s))$$

given by composition of the partial functions from states to states $\llbracket C \rrbracket, \llbracket C' \rrbracket : \text{State} \rightarrow \text{State}$ which are the denotations of the commands.

Cf. operational semantics of sequential composition:

$$\frac{C, s \Downarrow s' \quad C', s' \Downarrow s''}{C; C', s \Downarrow s''} .$$

Slide 10

1.2 Example: while-loops as fixed points

The requirement of *compositionality* mentioned on Slide 2 is quite a tough one. It means that the collection of mathematical objects we use to give denotations to program phases has to be sufficiently rich that it supports operations for modelling all the phrase-forming constructs of the programming language in question. Some phrase-forming constructs are easy to deal with, others less so. For example, conditional expressions involving state-manipulating commands can be given a denotational semantics in terms of a corresponding branching function applied to the denotations of the immediate subexpressions: see Slide 8. Similarly, the denotational semantics of the sequential composition of commands can be given by the operation of composition of partial functions from states to states, as shown on Slide 10.

We now proceed to consider the denotational semantics of the basic programming language IMP, obtained by extending IMP^- with **while**-loops:

$$C \in \mathbf{Comm} ::= \dots \mid \mathbf{while } B \mathbf{ do } C$$

However, this looping construct is not so easy to explain compositionally!

The transition semantics of a **while**-loop

$$\langle \mathbf{while } B \mathbf{ do } C, s \rangle \rightarrow \langle \mathbf{if } B \mathbf{ then } C; (\mathbf{while } B \mathbf{ do } C) \mathbf{ else skip}, s \rangle$$

suggests that its denotation as a partial function from states to states should satisfy

$$(1) \quad \llbracket \mathbf{while} \ B \ \mathbf{do} \ C \rrbracket = \llbracket \mathbf{if} \ B \ \mathbf{then} \ C; (\mathbf{while} \ B \ \mathbf{do} \ C) \ \mathbf{else} \ \mathbf{skip} \rrbracket.$$

Note that this cannot be used directly to define $\llbracket \mathbf{while} \ B \ \mathbf{do} \ C \rrbracket$, since the right-hand side contains as a subphrase the very phrase whose denotation we are trying to define. Using the denotational semantics of sequential composition and **if** (and using the fact that the denotation of **skip** is the identity function $\lambda s \in State.s$), (1) amounts to saying that $\llbracket \mathbf{while} \ B \ \mathbf{do} \ C \rrbracket$ should be a solution of the *fixed point equation* given on Slide 11.

Fixed point property of
 $\llbracket \mathbf{while} \ B \ \mathbf{do} \ C \rrbracket$

$\llbracket \mathbf{while} \ B \ \mathbf{do} \ C \rrbracket = f_{\llbracket B \rrbracket, \llbracket C \rrbracket}(\llbracket \mathbf{while} \ B \ \mathbf{do} \ C \rrbracket)$

where, for each $b : State \rightarrow \{true, false\}$ and $c : State \rightarrow State$, we define

$f_{b,c} : (State \rightarrow State) \rightarrow (State \rightarrow State)$

as

$f_{b,c} = \lambda w \in (State \rightarrow State). \lambda s \in State.$
 $if (b(s), w(c(s)), s).$

- Why does $w = f_{\llbracket B \rrbracket, \llbracket C \rrbracket}(w)$ have a solution?
- What if it has several solutions—which one do we take to be $\llbracket \mathbf{while} \ B \ \mathbf{do} \ C \rrbracket$?

Slide 11

Such fixed point equations arise very often in giving denotational semantics to languages with recursive features. Beginning with Dana Scott's pioneering work in the late 60's, a mathematical theory called *domain theory* has been developed to provide a setting in which not only can we always find solutions for the fixed point equations arising from denotational semantics, but also we can pick out solutions that are minimal in a suitable sense—and this turns out to ensure a good match between denotational and operational semantics. The key idea is to consider a partial order between the mathematical objects used as denotations—this partial order expresses the fact that one object is *approximated by*, or *carries more information than*, or is *more well-defined than* another one below it in the ordering. Then the minimal solution of a fixpoint equation can be constructed as the limit of an increasing chain of approximations to the solution. These ideas will be made

mathematically precise and general in the next section; but first we illustrate how they work out concretely for the particular problem on Slide 11.

For definiteness, let us consider the particular **while**-loop

(2) **while** $X > 0$ **do** ($Y := X * Y ; X := X - 1$)

where X and Y are two distinct integer storage locations (variables) and where the set of locations \mathbb{L} is $\{ X, Y \}$.

In this case we can just take a state to be an assignment $[X \mapsto x, Y \mapsto y]$ with $x, y \in \mathbb{Z}$, recording the current contents of the locations X and Y respectively. Thus, $State = (\mathbb{L} \rightarrow \mathbb{Z})$.

We are trying to define the denotation of (2) as a partial function

$$w : State \rightarrow State$$

that should be a solution to the fixed-point equation

$$w = f_{\llbracket X > 0 \rrbracket, \llbracket Y := X * Y ; X := X - 1 \rrbracket}(w)$$

on Slide 11.

For the particular boolean expression $B = (X > 0)$ and command $C = (Y := X * Y ; X := X - 1)$, the function $f_{\llbracket B \rrbracket, \llbracket C \rrbracket}$ coincides with the function f defined on Slide 12.

$\llbracket \text{while } X > 0 \text{ do } (Y := X * Y ; X := X - 1) \rrbracket$

Let

$State \stackrel{\text{def}}{=} (\mathbb{L} \rightarrow \mathbb{Z})$ integer assignments to locations

$D \stackrel{\text{def}}{=} (State \rightarrow State)$ partial functions on states

For $\llbracket \text{while } X > 0 \text{ do } Y := X * Y ; X := X - 1 \rrbracket \in D$ we seek a minimal solution to $w = f(w)$, where $f : D \rightarrow D$ is defined by:

$$\begin{aligned} f(w)([X \mapsto x, Y \mapsto y]) \\ = \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ w([X \mapsto x - 1, Y \mapsto x * y]) & \text{if } x > 0. \end{cases} \end{aligned}$$

$$D \stackrel{\text{def}}{=} (State \rightarrow State)$$

- **Partial order \sqsubseteq on D :**
 - $w \sqsubseteq w'$ iff for all $s \in State$, if w is defined at s then so is w' and moreover $w(s) = w'(s)$.
 - iff the graph of w is included in the graph of w' .
- **Least element $\perp \in D$ w.r.t. \sqsubseteq :**
 - \perp = totally undefined partial function
 - = partial function with empty graph
 - (satisfies $\perp \sqsubseteq w$, for all $w \in D$).

Slide 13

Consider the partial order, \sqsubseteq , between the elements of $D = (State \rightarrow State)$ given on Slide 13. Note that \sqsubseteq does embody the kind of ‘information ordering’ mentioned above: if $w \sqsubseteq w'$, then w' agrees with w wherever the latter is defined, but it may be defined at some other arguments as well. Note also that D contains an element which is least with respect to this partial order: for the totally undefined partial function, which we will write as \perp , satisfies $\perp \sqsubseteq w$ for any $w \in D$.

Starting with \perp , we apply the function f over and over again to build up a sequence of partial functions w_0, w_1, w_2, \dots :

$$\begin{cases} w_0 & \stackrel{\text{def}}{=} \perp \\ w_{n+1} & \stackrel{\text{def}}{=} f(w_n). \end{cases}$$

Using the definition of f on Slide 12, one finds that

$$w_1[X \mapsto x, Y \mapsto y] = f(\perp)[X \mapsto x, Y \mapsto y] = \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ \text{undefined} & \text{if } x \geq 1 \end{cases}$$

$$w_2[X \mapsto x, Y \mapsto y] = f(w_1)[X \mapsto x, Y \mapsto y] = \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ [X \mapsto 0, Y \mapsto y] & \text{if } x = 1 \\ \text{undefined} & \text{if } x \geq 2 \end{cases}$$

$$w_3[X \mapsto x, Y \mapsto y] = f(w_2)[X \mapsto x, Y \mapsto y] = \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ [X \mapsto 0, Y \mapsto y] & \text{if } x = 1 \\ [X \mapsto 0, Y \mapsto 2 * y] & \text{if } x = 2 \\ \text{undefined} & \text{if } x \geq 3 \end{cases}$$

$$w_4[X \mapsto x, Y \mapsto y] = f(w_3)[X \mapsto x, Y \mapsto y] = \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ [X \mapsto 0, Y \mapsto y] & \text{if } x = 1 \\ [X \mapsto 0, Y \mapsto 2 * y] & \text{if } x = 2 \\ [X \mapsto 0, Y \mapsto 6 * y] & \text{if } x = 3 \\ \text{undefined} & \text{if } x \geq 4 \end{cases}$$

and in general

$$w_n[X \mapsto x, Y \mapsto y] = \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ [X \mapsto 0, Y \mapsto (!x) * y] & \text{if } 0 < x < n \\ \text{undefined} & \text{if } x \geq n \end{cases}$$

where as usual, $!x$ is the factorial of x .

Thus we get an increasing sequence of partial functions

$$w_0 \sqsubseteq w_1 \sqsubseteq w_2 \sqsubseteq \dots \sqsubseteq w_n \sqsubseteq \dots$$

defined on larger and larger sets of states (x, y) and agreeing where they are defined.

The union of all these partial functions is the element $w_\infty \in D$ given by

$$w_\infty[X \mapsto x, Y \mapsto y] = \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ [X \mapsto 0, Y \mapsto (!x) * y] & \text{if } x > 0. \end{cases}$$

Note that w_∞ is a fixed point of the function f , since for all $[X \mapsto x, Y \mapsto y]$ we have

$$\begin{aligned} f(w_\infty)[X \mapsto x, Y \mapsto y] &= \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ w_\infty[X \mapsto x - 1, Y \mapsto x * y] & \text{if } x > 0 \end{cases} \quad (\text{by definition of } f) \\ &= \begin{cases} [X \mapsto x, Y \mapsto y] & \text{if } x \leq 0 \\ [X \mapsto 0, Y \mapsto 1 * y] & \text{if } x = 1 \\ [X \mapsto 0, Y \mapsto !(x - 1) * x * y] & \text{if } x > 1 \end{cases} \quad (\text{by definition of } w_\infty) \\ &= w_\infty[X \mapsto x, Y \mapsto y] . \end{aligned}$$

In fact one can show that w_∞ is the *least* fixed point of f , in the sense that for all $w \in D$

$$(3) \quad w = f(w) \quad \Rightarrow \quad w_\infty \sqsubseteq w.$$

This least fixed point w_∞ is what we take as the denotation of

while $X > 0$ **do** ($Y := X * Y ; X := X - 1$).

Its construction is an instance of Tarski's Fixed Point Theorem to be proved in the next section. Note also that w_∞ is indeed the function from states to states that we get from the structural operational semantics of the command **while** $X > 0$ **do** ($Y := X * Y ; X := X - 1$), as given in the Part IB course on **Semantics of Programming Languages**.

1.3 Exercises

Exercise 1.3.1. Implement the denotational semantics of IMP^- in SML.

Exercise 1.3.2. Consider the function

$$f_{b,c} : (\text{State} \rightarrow \text{State}) \rightarrow (\text{State} \rightarrow \text{State})$$

defined on Slide 11.

(i) Show by induction on n that

$$f_{b,c}^n(\perp) = \lambda s \in \text{State}. \begin{cases} c^k(s) & \text{if } 0 \leq k < n \text{ is such that } b(c^i(s)) = \text{true} \\ & \text{for all } 0 \leq i < k \text{ and } b(c^k(s)) = \text{false} \\ \text{undefined} & \text{if } b(c^i(s)) = \text{true} \text{ for all } 0 \leq i < n \end{cases}$$

(ii) Let $w_{b,c} : \text{State} \rightarrow \text{State}$ be the partial function defined as

$$w_{b,c} \stackrel{\text{def}}{=} \lambda s \in \text{State}. \begin{cases} c^k(s) & \text{if } k \geq 0 \text{ is such that } b(c^i(s)) = \text{true} \\ & \text{for all } 0 \leq i < k \text{ and } b(c^k(s)) = \text{false} \\ \text{undefined} & \text{if } b(c^i(s)) = \text{true} \text{ for all } i \geq 0 \end{cases}$$

Show that $w_{b,c}$ satisfies the fixed-point equation

$$w_{b,c} = f_{b,c}(w_{b,c}) .$$

(iii) Describe the function $f_{b,c}$ for $b = \llbracket \text{true} \rrbracket = \lambda s \in \text{State}. \text{true}$ and $c = \llbracket \text{skip} \rrbracket = \lambda s \in \text{State}. s$. Which partial functions from states to states are fixed points of this $f_{b,c}$? What is its least fixed point (with respect to the \sqsubseteq ordering defined above)? Does this least fixed point agree with the partial function from states to states determined by the operational semantics of **while true do skip**?

Exercise 1.3.3. Show that the relation \sqsubseteq defined on Slide 13 is a partial order with least element \perp .

Exercise 1.3.4. Prove the statement (3). More generally, with the definitions of Slide 13 and Exercise 1.3.2, prove that

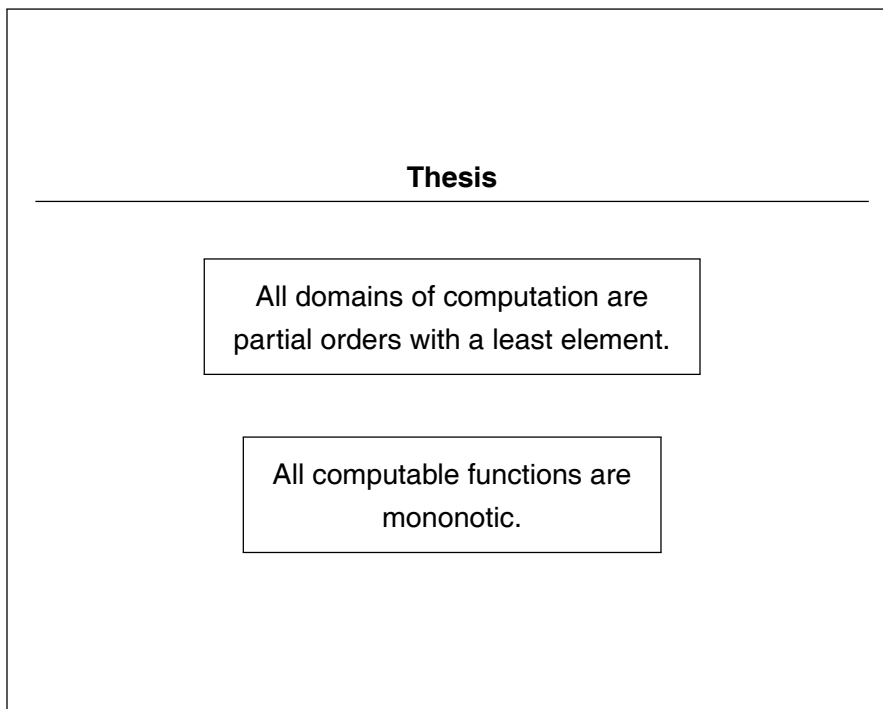

$$w = f_{b,c}(w) \implies w_{b,c} \sqsubseteq w$$

for all $w \in (\text{State} \rightarrow \text{State})$.

2 Least Fixed Points

This section introduces a mathematical theory, *domain theory*, which amongst other things provides a general framework for constructing the least fixed points used in the denotational semantics of various programming language features. The theory was introduced by Dana Scott.

2.1 Posets and monotone functions

Slide 14

2.1.1 Posets

Domain theory makes use of partially ordered sets satisfying certain completeness properties. The definition of a *partial order* is recalled on Slide 15. D is called the *underlying set* of the poset (D, \sqsubseteq) . Most of the time we will refer to posets just by naming their underlying sets and use the same symbol \sqsubseteq to denote the partial order in a variety of different posets.

Partially ordered sets

A binary relation \sqsubseteq on a set D is a *partial order* iff it is

reflexive: $\forall d \in D. d \sqsubseteq d$

transitive: $\forall d, d', d'' \in D. d \sqsubseteq d' \sqsubseteq d'' \Rightarrow d \sqsubseteq d''$

anti-symmetric: $\forall d, d' \in D. d \sqsubseteq d' \sqsubseteq d \Rightarrow d = d'$.

Such a pair (D, \sqsubseteq) is called a *partially ordered set*, or *poset*.

Slide 15

$$\frac{}{x \sqsubseteq x}$$

$$\frac{x \sqsubseteq y \quad y \sqsubseteq z}{x \sqsubseteq z}$$

$$\frac{x \sqsubseteq y \quad y \sqsubseteq x}{x = y}$$

Slide 16

Domain of partial functions, $X \rightarrow Y$

Underlying set: all partial functions, f , with domain of definition $\text{dom}(f) \subseteq X$ and taking values in Y .

Partial order:

$$\begin{aligned} f \sqsubseteq g & \text{ iff } \text{dom}(f) \subseteq \text{dom}(g) \text{ and} \\ & \forall x \in \text{dom}(f). f(x) = g(x) \\ & \text{ iff } \text{graph}(f) \subseteq \text{graph}(g) \end{aligned}$$

Slide 17

Monotonicity

- A function $f : D \rightarrow E$ between posets is *monotone* iff $\forall d, d' \in D. d \sqsubseteq d' \Rightarrow f(d) \sqsubseteq f(d')$.

$$\frac{x \sqsubseteq y}{f(x) \sqsubseteq f(y)} \quad (f \text{ monotone})$$

Slide 18

Example 2.1.1. The set $(X \rightarrow Y)$ of all partial functions from a set X to a set Y can be made into a poset, as indicated on Slide 17. It was this domain for the case $X = Y = \text{State}$ (some set of states) that we used for the denotation of commands in Section 1.2.

2.1.2 Monotone functions

The notion of mapping between posets is given in Slide 18.

Example 2.1.2. Given posets D and E , for each $e \in E$ it is easy to see that the *constant function* $D \rightarrow E$ with value e , $\lambda d \in D . e$, is monotone.

Example 2.1.3. When D is the domain of partial functions $(\text{State} \rightarrow \text{State})$ (cf. Slide 17), the function $f_{b,c} : D \rightarrow D$ defined on Slide 11 in connection with the denotational semantics of **while**-loops is a monotone function. We leave the verification of this as an exercise.

2.2 Least elements and pre-fixed points

Definition 2.2.1. Suppose that D is a poset and that S is a subset of D . An element $d \in S$ is the *least* element of S if it satisfies

$$\forall x \in S. d \sqsubseteq x .$$

Note that because \sqsubseteq is anti-symmetric, S has at most one least element. Note also that a poset may not have least element. For example, \mathbb{Z} with its usual partial order does not have a least element.

A *fixed point* for a function $f : D \rightarrow D$ is by definition an element $d \in D$ satisfying $f(d) = d$. If D is a poset, we can consider a weaker notion, of *pre-fixed point*, as defined on Slide 19.

Pre-fixed points

Let D be a poset and $f : D \rightarrow D$ be a function.

An element $d \in D$ is a *pre-fixed point* of f if it satisfies $f(d) \sqsubseteq d$.

The *least pre-fixed point* of f , if it exists, will be written

$$\boxed{fix(f)}$$

It is thus (uniquely) specified by the two properties:

$$(lfp1) \quad f(fix(f)) \sqsubseteq fix(f)$$

$$(lfp2) \quad \forall d \in D. f(d) \sqsubseteq d \Rightarrow fix(f) \sqsubseteq d.$$

Slide 19

Proof principle

1.

$$\frac{}{f(fix(f)) \sqsubseteq fix(f)}$$

2. Let D be a poset and let $f : D \rightarrow D$ be a function with a least pre-fixed point $fix(f) \in D$.

For all $x \in D$, to prove that $fix(f) \sqsubseteq x$ it is enough to establish that $f(x) \sqsubseteq x$.

$$\frac{f(x) \sqsubseteq x}{fix(f) \sqsubseteq x}$$

Slide 20

Proposition 2.2.2. *Suppose D is a poset and $f : D \rightarrow D$ is a function possessing a least pre-fixed point, $fix(f)$, as defined on Slide 19.*

Provided f is monotone, $fix(f)$ is in particular a fixed point for f (and hence is the least element of the set of fixed points for f).

Proof. By definition, $fix(f)$ satisfies property (lfp1) on Slide 19. If f is monotone (Slide 18) we can apply f to both sides of (lfp1) to conclude that

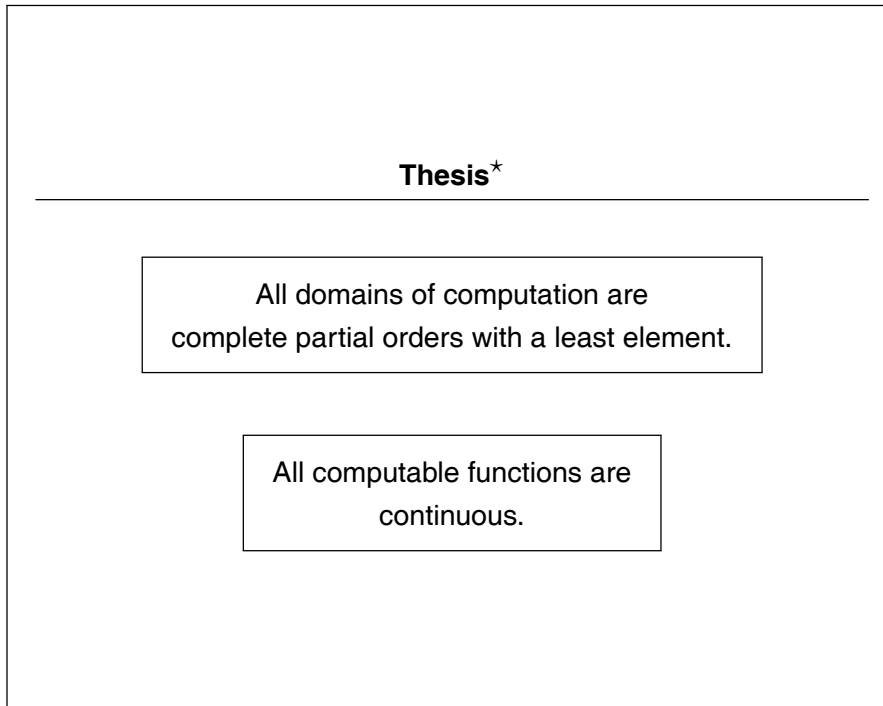

$$f(f(fix(f))) \sqsubseteq f(fix(f)).$$

Then applying property (lfp2) with $d = f(fix(f))$, we get that

$$fix(f) \sqsubseteq f(fix(f)).$$

Combining this with (lfp1) and the anti-symmetry property of the partial order \sqsubseteq , we get $f(fix(f)) = fix(f)$, as required. \square

2.3 Cpo's and continuous functions

Slide 21

2.3.1 Domains

Definition 2.3.1. (i) If it exists, we will write the least element of a poset D as \perp_D , or just \perp when D is understood from the context. Thus \perp is uniquely determined by the property:

$$\forall d \in D. \perp \sqsubseteq d.$$

The least element of a poset is sometimes called its *bottom* element.

(ii) A countable, increasing *chain* in a poset D is a sequence of elements of D satisfying

$$d_0 \sqsubseteq d_1 \sqsubseteq d_2 \sqsubseteq \dots$$

An *upper bound* for the chain is any $d \in D$ satisfying $\forall n \in \mathbb{N}. d_n \sqsubseteq d$. If it exists, the *least upper bound*, or *lub*, of the chain will be written as

$$\bigsqcup_{n \geq 0} d_n.$$

Thus by definition:

- $\forall m \in \mathbb{N}. d_m \sqsubseteq \bigsqcup_{n \geq 0} d_n.$
- For any $d \in D$, if $\forall m \in \mathbb{N}. d_m \sqsubseteq d$, then $\bigsqcup_{n \geq 0} d_n \sqsubseteq d.$

Remark 2.3.2. The following points should be noted.

- (i) We will not need to consider uncountable, or decreasing chains in a poset: so a ‘chain’ will always mean a countable, increasing chain.
- (ii) Like the least element of any subset of a poset, the lub of a chain is unique if it exists. (It does not have to exist: for example the chain $0 \leq 1 \leq 2 \leq \dots$ in \mathbb{N} has no upper bound, hence no lub.)
- (iii) A least upper bound is sometimes called a *supremum*. Some other common notations for $\bigsqcup_{n \geq 0} d_n$ are:

$$\bigsqcup_{n=0}^{\infty} d_n \quad \text{and} \quad \bigsqcup \{d_n \mid n \geq 0\} .$$

- (iv) The elements of a chain do not necessarily have to be distinct. In particular, we say that a chain $d_0 \sqsubseteq d_1 \sqsubseteq d_2 \sqsubseteq \dots$ is *eventually constant* if for some $N \in \mathbb{N}$ it is the case that $\forall n \geq N. d_n = d_N$. Note that in this case $\bigsqcup_{n \geq 0} d_n = d_N$.
- (v) If we discard any finite number of elements at the beginning of a chain, we do not affect its set of upper bounds and hence do not change its lub:

$$\bigsqcup_{n \geq 0} d_n = \bigsqcup_{n \geq 0} d_{N+n}, \quad \text{for any } N \in \mathbb{N}.$$

Cpo's and domains

A *chain complete poset*, or *cpo* for short, is a poset (D, \sqsubseteq) in which all countable increasing chains $d_0 \sqsubseteq d_1 \sqsubseteq d_2 \sqsubseteq \dots$ have least upper bounds, $\bigsqcup_{n \geq 0} d_n$:

$$\text{(lub1)} \quad \forall m \geq 0. d_m \sqsubseteq \bigsqcup_{n \geq 0} d_n$$

$$\text{(lub2)} \quad \forall d \in D. (\forall m \geq 0. d_m \sqsubseteq d) \Rightarrow \bigsqcup_{n \geq 0} d_n \sqsubseteq d.$$

A *domain* is a cpo that possesses a least element, \perp :

$$\forall d \in D. \perp \sqsubseteq d.$$

Slide 22

$$\frac{}{\perp \sqsubseteq x}$$

$$\frac{}{x_i \sqsubseteq \bigsqcup_{n \geq 0} x_n} \quad (i \geq 0 \text{ and } \langle x_n \rangle \text{ a chain})$$

$$\frac{\forall n \geq 0. x_n \sqsubseteq x}{\bigsqcup_{n \geq 0} x_n \sqsubseteq x} \quad (\langle x_i \rangle \text{ a chain})$$

Slide 23

In this course we will be concerned with posets enjoying certain completeness properties, as defined on Slide 22. It should be noted that the term ‘domain’ is used rather loosely in the literature on denotational semantics: there are many different kinds of domain, enjoying various extra order-theoretic properties over and above the rather minimal ones of chain-completeness and possession of a least element that we need for this course.

Example 2.3.3. The set $(X \rightarrow Y)$ of all partial functions from a set X to a set Y can be made into a domain, as indicated on Slide 24. It was this domain for the case $X = Y = \text{State}$ (some set of states) that we used for the denotation of commands in Section 1.2. Note that the f which is claimed to be the lub of $f_0 \sqsubseteq f_1 \sqsubseteq f_2 \sqsubseteq \dots$ on Slide 24 is a well-defined partial function because the f_n agree where they are defined. We leave it as an exercise to check that this f is indeed the least upper bound of $f_0 \sqsubseteq f_1 \sqsubseteq f_2 \sqsubseteq \dots$ in the poset $(X \rightarrow Y, \sqsubseteq)$.

Domain of partial functions, $X \rightarrow Y$

Underlying set: all partial functions, f , with domain of definition $dom(f) \subseteq X$ and taking values in Y .

Partial order:

$$f \sqsubseteq g \quad \text{iff} \quad \begin{aligned} & dom(f) \subseteq dom(g) \text{ and} \\ & \forall x \in dom(f). f(x) = g(x) \\ & \text{iff} \quad graph(f) \subseteq graph(g) \end{aligned}$$

Lub of chain $f_0 \sqsubseteq f_1 \sqsubseteq f_2 \sqsubseteq \dots$ is the partial function f with $dom(f) = \bigcup_{n \geq 0} dom(f_n)$ and

$$f(x) = \begin{cases} f_n(x) & \text{if } x \in dom(f_n), \text{ some } n \\ \text{undefined} & \text{otherwise} \end{cases}$$

Least element \perp is the totally undefined partial function.

Slide 24

Example 2.3.4. Any poset (D, \sqsubseteq) whose underlying set D is finite is a cpo. For in such a poset any chain is eventually constant and we noted in Remark 2.3.2(iv) that such a chain always possesses a lub. Of course, a finite poset need not have a least element, and hence need not be a domain—for example, consider the poset with Hasse diagram

(The *Hasse diagram* of a poset is the directed graph whose vertices are the elements of the underlying set of the poset and in which there is an edge from vertex x to vertex y iff $x \neq y$ and $\forall z. (x \sqsubseteq z \ \& \ z \sqsubseteq y) \Rightarrow (z = x \vee z = y)$.)

Figure 1 shows two very simple, but infinite domains. Here are two examples of posets that are not cpos.

Example 2.3.5. The set of natural numbers $\mathbb{N} = \{0, 1, 2, \dots\}$ equipped with the usual partial order, \leq , is not a cpo. For the increasing chain $0 \leq 1 \leq 2 \leq \dots$ has no upper bound in \mathbb{N} .

Example 2.3.6. Consider a modified version of the second example in Figure 1 in which we adjoin two different upper bounds, $\omega_1 \neq \omega_2$, for \mathbb{N} . In other words,

The 'flat natural numbers', \mathbb{N}_\perp :

The 'vertical natural numbers', Ω :

Figure 1: Two domains

consider $D \stackrel{\text{def}}{=} \mathbb{N} \cup \{\omega_1, \omega_2\}$ with partial order \sqsubseteq defined by:

$$d \sqsubseteq d' \stackrel{\text{def}}{\iff} \begin{cases} d, d' \in \mathbb{N} \ \& \ d \leq d', \\ \text{or} \ d \in \mathbb{N} \ \& \ d' \in \{\omega_1, \omega_2\}, \\ \text{or} \ d = d' = \omega_1, \\ \text{or} \ d = d' = \omega_2. \end{cases}$$

Then the increasing chain $0 \sqsubseteq 1 \sqsubseteq 2 \sqsubseteq \dots$ in D has two upper bounds (ω_1 and ω_2), but no least one (since $\omega_1 \not\sqsubseteq \omega_2$ and $\omega_2 \not\sqsubseteq \omega_1$). So (D, \sqsubseteq) is not a cpo.

Some properties of lubs of chains

Let D be a cpo.

1. For $d \in D$, $\bigsqcup_n d = d$.
2. For every chain $d_0 \sqsubseteq d_1 \sqsubseteq \dots \sqsubseteq d_n \sqsubseteq \dots$ in D ,

$$\bigsqcup_n d_n = \bigsqcup_n d_{N+n}$$

for all $N \in \mathbb{N}$.

Slide 25

3. For every pair of chains $d_0 \sqsubseteq d_1 \sqsubseteq \dots \sqsubseteq d_n \sqsubseteq \dots$ and $e_0 \sqsubseteq e_1 \sqsubseteq \dots \sqsubseteq e_n \sqsubseteq \dots$ in D ,
if $d_n \sqsubseteq e_n$ for all $n \in \mathbb{N}$ then $\bigsqcup_n d_n \sqsubseteq \bigsqcup_n e_n$.

$$\frac{\forall n \geq 0 . x_n \sqsubseteq y_n}{\bigsqcup_n x_n \sqsubseteq \bigsqcup_n y_n} \quad (\langle x_n \rangle \text{ and } \langle y_n \rangle \text{ chains})$$

Slide 26

Diagonalising a double chain

Lemma. Let D be a cpo. Suppose that the doubly-indexed family of elements $d_{m,n} \in D$ ($m, n \geq 0$) satisfies

$$(\dagger) \quad m \leq m' \ \& \ n \leq n' \Rightarrow d_{m,n} \sqsubseteq d_{m',n'}.$$

Then

$$\bigsqcup_{n \geq 0} d_{0,n} \sqsubseteq \bigsqcup_{n \geq 0} d_{1,n} \sqsubseteq \bigsqcup_{n \geq 0} d_{2,n} \sqsubseteq \dots$$

and

$$\bigsqcup_{m \geq 0} d_{m,0} \sqsubseteq \bigsqcup_{m \geq 0} d_{m,1} \sqsubseteq \bigsqcup_{m \geq 0} d_{m,3} \sqsubseteq \dots$$

Moreover

$$\bigsqcup_{m \geq 0} \left(\bigsqcup_{n \geq 0} d_{m,n} \right) = \bigsqcup_{k \geq 0} d_{k,k} = \bigsqcup_{n \geq 0} \left(\bigsqcup_{m \geq 0} d_{m,n} \right).$$

Slide 27

Proof of the Lemma on Slide 27. We make use of the defining properties of lubs of chains—(lub1) and (lub2) on Slide 22. First note that if $m \leq m'$ then

$$\begin{aligned} d_{m,n} &\sqsubseteq d_{m',n} && \text{by property } (\dagger) \text{ of the } d_{m,n} \\ &\sqsubseteq \bigsqcup_{n' \geq 0} d_{m',n'} && \text{by (lub1)} \end{aligned}$$

for all $n \geq 0$, and hence $\bigsqcup_{n \geq 0} d_{m,n} \sqsubseteq \bigsqcup_{n' \geq 0} d_{m',n'}$ by (lub2). Thus we do indeed get a chain of lubs

$$\bigsqcup_{n \geq 0} d_{0,n} \sqsubseteq \bigsqcup_{n \geq 0} d_{1,n} \sqsubseteq \bigsqcup_{n \geq 0} d_{2,n} \sqsubseteq \dots$$

and can form its lub, $\bigsqcup_{m \geq 0} \bigsqcup_{n \geq 0} d_{m,n}$. Using property (lub1) twice we have

$$d_{k,k} \sqsubseteq \bigsqcup_{n \geq 0} d_{k,n} \sqsubseteq \bigsqcup_{m \geq 0} \bigsqcup_{n \geq 0} d_{m,n}$$

for each $k \geq 0$, and hence by (lub2)

$$(4) \quad \bigsqcup_{k \geq 0} d_{k,k} \sqsubseteq \bigsqcup_{m \geq 0} \bigsqcup_{n \geq 0} d_{m,n}.$$

Conversely, for each $m, n \geq 0$, note that

$$\begin{aligned} d_{m,n} &\sqsubseteq d_{\max\{m,n\}, \max\{m,n\}} && \text{by property } (\dagger) \\ &\sqsubseteq \bigsqcup_{k \geq 0} d_{k,k} && \text{by (lub1)} \end{aligned}$$

and hence applying (lub2) twice we have

$$(5) \quad \bigsqcup_{m \geq 0} \bigsqcup_{n \geq 0} d_{m,n} \sqsubseteq \bigsqcup_{k \geq 0} d_{k,k}.$$

Combining (4) and (5) with the anti-symmetry property of \sqsubseteq yields the desired equality. We obtain the additional equality by the same argument but interchanging the roles of m and n . \square

2.3.2 Continuous functions

Continuity and strictness

- If D and E are cpo's, the function f is *continuous* iff
 1. it is monotone, and
 2. it preserves lubs of chains, *i.e.* for all chains $d_0 \sqsubseteq d_1 \sqsubseteq \dots$ in D , it is the case that

$$f\left(\bigsqcup_{n \geq 0} d_n\right) = \bigsqcup_{n \geq 0} f(d_n) \quad \text{in } E.$$

- If D and E have least elements, then the function f is *strict* iff $f(\perp) = \perp$.

Slide 28

Remark 2.3.7. Note that if $f : D \rightarrow E$ is monotone and $d_0 \sqsubseteq d_1 \sqsubseteq d_2 \sqsubseteq \dots$ is a chain in D , then applying f we get a chain $f(d_0) \sqsubseteq f(d_1) \sqsubseteq f(d_2) \sqsubseteq \dots$ in E . Moreover, if d is an upper bound of the first chain, then $f(d)$ is an upper bound of the second and hence is greater than its lub. Hence if $f : D \rightarrow E$ is a monotone

function between cpo's, we always have

$$\bigsqcup_{n \geq 0} f(d_n) \sqsubseteq f(\bigsqcup_{n \geq 0} d_n)$$

Therefore (using the antisymmetry property of \sqsubseteq), to check that a monotone function f between cpo's is continuous, it suffices to check for each chain $d_0 \sqsubseteq d_1 \sqsubseteq d_2 \sqsubseteq \dots$ in D that

$$f(\bigsqcup_{n \geq 0} d_n) \sqsubseteq \bigsqcup_{n \geq 0} f(d_n)$$

holds in E .

Example 2.3.8. Given cpo's D and E , for each $e \in E$ it is easy to see that the constant function $D \rightarrow E$ with value e , $\lambda d \in D. e$, is continuous.

Example 2.3.9. When D is the domain of partial functions ($State \rightarrow State$) (cf. Slide 24), the function $f_{b,c} : D \rightarrow D$ defined on Slide 11 in connection with the denotational semantics of **while**-loops is a continuous function. We leave the verification of this as an exercise.

Example 2.3.10. Let Ω be the domain of vertical natural numbers, as defined in Figure 1. Then the function $f : \Omega \rightarrow \Omega$ defined by

$$\begin{cases} f(n) = 0 & (n \in \mathbb{N}) \\ f(\omega) = \omega. \end{cases}$$

is monotone and strict, but it is not continuous because

$$f(\bigsqcup_{n \geq 0} n) = f(\omega) = \omega \neq 0 = \bigsqcup_{n \geq 0} 0 = \bigsqcup_{n \geq 0} f(n).$$

2.4 Tarski's fixed point theorem

Tarski's Fixed Point Theorem

Let $f : D \rightarrow D$ be a continuous function on a domain D . Then

- f possesses a least pre-fixed point, given by

$$fix(f) = \bigsqcup_{n \geq 0} f^n(\perp).$$

- Moreover, $fix(f)$ is a fixed point of f , i.e. satisfies $f(fix(f)) = fix(f)$, and hence is the *least fixed point* of f .

Slide 29

Slide 29 gives the key result about continuous functions on domains which permits us to give denotational semantics of programs involving recursive features. The notation $f^n(\perp)$ used on the slide is defined as follows:

$$(6) \quad \begin{cases} f^0(\perp) & \stackrel{\text{def}}{=} \perp \\ f^{n+1}(\perp) & \stackrel{\text{def}}{=} f(f^n(\perp)). \end{cases}$$

Note that since $\forall d \in D. \perp \sqsubseteq d$, one has $f^0(\perp) = \perp \sqsubseteq f^1(\perp)$; and by monotonicity of f

$$f^n(\perp) \sqsubseteq f^{n+1}(\perp) \Rightarrow f^{n+1}(\perp) = f(f^n(\perp)) \sqsubseteq f(f^{n+1}(\perp)) = f^{n+2}(\perp).$$

Therefore, by induction on $n \in \mathbb{N}$, it is the case that $\forall n \in \mathbb{N}. f^n(\perp) \sqsubseteq f^{n+1}(\perp)$. In other words the elements $f^n(\perp)$ do form a chain in D . So since D is a cpo, the least upper bound used to define $fix(f)$ on Slide 29 does make sense.

Proof of Tarski's Fixed Point Theorem. First note that

$$\begin{aligned}
 f(\text{fix}(f)) &= f\left(\bigsqcup_{n \geq 0} f^n(\perp)\right) \\
 &= \bigsqcup_{n \geq 0} f(f^n(\perp)) && \text{by continuity of } f \\
 &= \bigsqcup_{n \geq 0} f^{n+1}(\perp) && \text{by (6)} \\
 &= \bigsqcup_{n \geq 0} f^n(\perp) && \text{by Remark 2.3.2(v)} \\
 &= \text{fix}(f).
 \end{aligned}$$

So $\text{fix}(f)$ is indeed a fixed point for f and hence in particular satisfies condition (lfp1) on Slide 19. To verify the second condition (lfp2) needed for a least pre-fixed point, suppose that $d \in D$ satisfies $f(d) \sqsubseteq d$. Then since \perp is least in D

$$f^0(\perp) = \perp \sqsubseteq d$$

and

$$\begin{aligned}
 f^n(\perp) \sqsubseteq d \Rightarrow f^{n+1}(\perp) = f(f^n(\perp)) &\sqsubseteq f(d) && \text{monotonicity of } f \\
 &\sqsubseteq d && \text{by assumption on } d.
 \end{aligned}$$

Hence by induction on $n \in \mathbb{N}$ we have $\forall n \in \mathbb{N}. f^n(\perp) \sqsubseteq d$. Therefore d is an upper bound for the chain and hence lies above the least such, i.e.

$$\text{fix}(f) = \bigsqcup_{n \geq 0} f^n(\perp) \sqsubseteq d$$

as required for (lfp2). □

Example 2.4.1. The function $f_{\llbracket B \rrbracket, \llbracket C \rrbracket}$ defined on Slide 11 is a continuous function (Exercise 2.5.3) on the domain $(\text{State} \rightarrow \text{State})$ (Slide 24). So we can apply the Fixed Point Theorem and define $\llbracket \text{while } B \text{ do } C \rrbracket$ to be $\text{fix}(f_{\llbracket B \rrbracket, \llbracket C \rrbracket})$. In particular, the method used to construct the partial function w_∞ at the end of Section 1.2 is an instance of the method used in the proof of the Fixed Point Theorem to construct least pre-fixed points.

[[while B do C]]

[[while B do C]]
 $= fix(f_{[[B],[C]])}$
 $= \bigsqcup_{n \geq 0} f_{[[B],[C]]}^n(\perp)$
 $= \lambda s \in State.$

$$\left\{ \begin{array}{l} [[C]]^k(s) \quad \text{if } k \geq 0 \text{ is such that } [[B]]([[C]]^k(s)) = false \\ \quad \quad \quad \text{and } [[B]]([[C]]^i(s)) = true \text{ for all } 0 \leq i < k \\ \\ undefined \quad \text{if } [[B]]([[C]]^i(s)) = true \text{ for all } i \geq 0 \end{array} \right.$$

Slide 30

2.5 Exercises

Exercise 2.5.1. Verify the claims implicit on Slide 24: that the relation \sqsubseteq defined there is a partial order; that f is indeed the lub of the chain $f_0 \sqsubseteq f_1 \sqsubseteq f_2 \sqsubseteq \dots$; and that the totally undefined partial function is the least element.

Exercise 2.5.2. Prove the claims in Slides 25 and 27.

Exercise 2.5.3. Verify the claim made in Example 2.3.9 that $f_{b,c}$ is continuous. When is it strict?

3 Constructions on Domains

In this section we give various ways of building domains and continuous functions, concentrating on the ones that will be needed for a denotational semantics of the programming language PCF studied in the second half of the course. Note that to specify a cpo one must *define* a set equipped with a binary relation and then *prove*

- (i) the relation is a partial order;
- (ii) lubs exist for all chains in the partially ordered set.

Furthermore, for the cpo to be a domain, one just has to prove

- (iii) there is a least element.

Note that since lubs of chains and least elements are unique if they exist, a cpo or domain is completely determined by its underlying set and partial order. In what follows we will give various recipes for constructing cpos and domains and leave as an exercise the task of checking that properties (i), (ii), and (iii) do hold.

3.1 Flat domains

In order to model the PCF ground types *nat* and *bool*, we will use the notion of *flat domain* given on Slide 31.

Discrete cpo's and flat domains

For any set X , the relation of equality

$$x \sqsubseteq x' \stackrel{\text{def}}{\Leftrightarrow} x = x' \quad (x, x' \in X)$$

makes (X, \sqsubseteq) into a cpo, called the *discrete* cpo with underlying set X .

Let $X_{\perp} \stackrel{\text{def}}{=} X \cup \{\perp\}$, where \perp is some element not in X . Then

$$d \sqsubseteq d' \stackrel{\text{def}}{\Leftrightarrow} (d = d') \vee (d = \perp) \quad (d, d' \in X_{\perp})$$

makes (X_{\perp}, \sqsubseteq) into a domain (with least element \perp), called the *flat* domain determined by X .

The flat domain of natural numbers, \mathbb{N}_\perp , is pictured in Figure 1; the flat domain of booleans, \mathbb{B}_\perp looks like:

The following instances of continuous functions involving flat domains will also be needed for the denotational semantics of PCF. We leave the proofs as exercises.

Proposition 3.1.1. *Let $f : X \rightarrow Y$ be a partial function between two sets. Then*

$$f_\perp : X_\perp \rightarrow Y_\perp$$

$$f_\perp(d) \stackrel{\text{def}}{=} \begin{cases} f(d) & \text{if } d \in X \text{ and } f \text{ is defined at } d \\ \perp & \text{if } d \in X \text{ and } f \text{ is not defined at } d \\ \perp & \text{if } d = \perp \end{cases}$$

defines a continuous function between the corresponding flat domains.

3.2 Products of domains

Binary product of cpo's and domains

The *product* of two cpo's (D_1, \sqsubseteq_1) and (D_2, \sqsubseteq_2) has underlying set

$$D_1 \times D_2 = \{(d_1, d_2) \mid d_1 \in D_1 \ \& \ d_2 \in D_2\}$$

and partial order \sqsubseteq defined by

$$(d_1, d_2) \sqsubseteq (d'_1, d'_2) \stackrel{\text{def}}{\iff} d_1 \sqsubseteq_1 d'_1 \ \& \ d_2 \sqsubseteq_2 d'_2$$

Lubs of chains are calculated componentwise:

$$\bigsqcup_{n \geq 0} (d_{1,n}, d_{2,n}) = \left(\bigsqcup_{i \geq 0} d_{1,i}, \bigsqcup_{j \geq 0} d_{2,j} \right).$$

If (D_1, \sqsubseteq_1) and (D_2, \sqsubseteq_2) are domains so is $(D_1 \times D_2, \sqsubseteq)$ and $\perp_{D_1 \times D_2} = (\perp_{D_1}, \perp_{D_2})$.

Proposition 3.2.1 (Projections and pairing). *Let D_1 and D_2 be cpo's. The projections*

$$\begin{aligned} \pi_1 : D_1 \times D_2 &\rightarrow D_1 & \pi_2 : D_1 \times D_2 &\rightarrow D_2 \\ \pi_1(d_1, d_2) &\stackrel{\text{def}}{=} d_1 & \pi_2(d_1, d_2) &\stackrel{\text{def}}{=} d_2 \end{aligned}$$

are continuous functions. If $f_1 : D \rightarrow D_1$ and $f_2 : D \rightarrow D_2$ are continuous functions from a cpo D , then

$$\begin{aligned} \langle f_1, f_2 \rangle : D &\rightarrow D_1 \times D_2 \\ \langle f_1, f_2 \rangle(d) &\stackrel{\text{def}}{=} (f_1(d), f_2(d)) \end{aligned}$$

is continuous.

Proof. Continuity of these functions follows immediately from the characterisation of lubs of chains in $D_1 \times D_2$ given on Slide 32. \square

Proposition 3.2.2. *For each domain D the function*

$$\begin{aligned} \text{if} : \mathbb{B}_\perp \times (D \times D) &\rightarrow D \\ \text{if}(x, (d, d')) &\stackrel{\text{def}}{=} \begin{cases} d & \text{if } x = \text{true} \\ d' & \text{if } x = \text{false} \\ \perp_D & \text{if } x = \perp \end{cases} \end{aligned}$$

is continuous.

We will need the following generalised version of the product construction.

Definition 3.2.3 (Dependent products). Given a set I , suppose that for each $i \in I$ we are given a cpo (D_i, \sqsubseteq_i) . The *product* of this whole family of cpo's has

- underlying set equal to the I -fold cartesian product, $\prod_{i \in I} D_i$, of the sets D_i —so it consists of all functions p defined on I and such that the value of p at each $i \in I$ is an element $p(i) \in D_i$ of the cpo D_i ;
- partial order \sqsubseteq defined by

$$p \sqsubseteq p' \stackrel{\text{def}}{\iff} \forall i \in I. p(i) \sqsubseteq_i p'(i).$$

As for the binary product (which is the particular case when I is a two-element set), lubs in $(\prod_{i \in I} D_i, \sqsubseteq)$ can be calculated componentwise: if $p_0 \sqsubseteq p_1 \sqsubseteq p_2 \sqsubseteq \dots$ is a chain in the product cpo, its lub is the function mapping each $i \in I$ to the lub in D_i of the chain $p_0(i) \sqsubseteq p_1(i) \sqsubseteq p_2(i) \sqsubseteq \dots$. Thus

$$\left(\bigsqcup_{n \geq 0} p_n \right)(i) = \bigsqcup_{n \geq 0} p_n(i) \quad (i \in I).$$

In particular, for each $i \in I$ the i th *projection function*

$$\pi_i : \prod_{j \in I} D_j \rightarrow D_i$$

$$\pi_i(p) \stackrel{\text{def}}{=} p(i)$$

is continuous. If all the D_i are domains, then so is their product—the least element being the function mapping each $i \in I$ to the least element of D_i .

Continuous functions of two arguments

Proposition. *Let D, E, F be cpo's. A function $f : (D \times E) \rightarrow F$ is monotone if and only if it is monotone in each argument separately:*

$$\forall d, d' \in D, e \in E. d \sqsubseteq d' \Rightarrow f(d, e) \sqsubseteq f(d', e)$$

$$\forall d \in D, e, e' \in E. e \sqsubseteq e' \Rightarrow f(d, e) \sqsubseteq f(d, e').$$

Moreover, it is continuous if and only if it preserves lubs of chains in each argument separately:

$$f\left(\bigsqcup_{m \geq 0} d_m, e\right) = \bigsqcup_{m \geq 0} f(d_m, e)$$

$$f\left(d, \bigsqcup_{n \geq 0} e_n\right) = \bigsqcup_{n \geq 0} f(d, e_n).$$

- A couple of derived rules:

$$\frac{x \sqsubseteq x' \quad y \sqsubseteq y'}{f(x, y) \sqsubseteq f(x', y')} \quad (f \text{ monotone})$$

$$f(\bigsqcup_m x_m, \bigsqcup_n y_n) = \bigsqcup_k f(x_k, y_k)$$

Slide 34

Proof of the Proposition on Slide 33. The ‘only if’ direction is straightforward; its proof rests on the simple observations that if $d \sqsubseteq d'$ then $(d, e) \sqsubseteq (d', e)$, and $(\bigsqcup_{m \geq 0} d_m, e) = \bigsqcup_{m \geq 0} (d_m, e)$, as well as the companion facts for the right argument. For the ‘if’ direction, suppose first that f is monotone in each argument separately. Then given $(d, e) \sqsubseteq (d', e')$ in $D \times E$, by definition of the partial order on the binary product we have $d \sqsubseteq d'$ in D and $e \sqsubseteq e'$ in E . Hence

$$\begin{aligned} f(d, e) &\sqsubseteq f(d', e) && \text{by monotonicity in first argument} \\ &\sqsubseteq f(d', e') && \text{by monotonicity in second argument} \end{aligned}$$

and therefore by transitivity, $f(d, e) \sqsubseteq f(d', e')$, as required for monotonicity of f .

Now suppose f is continuous in each argument separately. Then given a chain

$(d_0, e_0) \sqsubseteq (d_1, e_1) \sqsubseteq (d_2, e_2) \sqsubseteq \dots$ in the binary product, we have

$$\begin{aligned}
 f\left(\bigsqcup_{n \geq 0} (d_n, e_n)\right) &= f\left(\bigsqcup_{i \geq 0} d_i, \bigsqcup_{j \geq 0} e_j\right) && \text{(cf. Slide 32)} \\
 &= \bigsqcup_{i \geq 0} f(d_i, \bigsqcup_{j \geq 0} e_j) && \text{by continuity in first argument} \\
 &= \bigsqcup_{i \geq 0} \left(\bigsqcup_{j \geq 0} f(d_i, e_j) \right) && \text{by continuity in second argument} \\
 &= \bigsqcup_{n \geq 0} f(d_n, e_n) && \text{by lemma on Slide 27}
 \end{aligned}$$

as required for continuity of f . □

3.3 Function domains

The set of continuous functions between two cpo's/domains can be made into a cpo/domain as shown on Slide 35. The terminology 'exponential cpo/domain' is sometimes used instead of 'function cpo/domain'.

Function cpo's and domains

Given cpo's (D, \sqsubseteq_D) and (E, \sqsubseteq_E) , the *function cpo* $(D \rightarrow E, \sqsubseteq)$ has underlying set

$$(D \rightarrow E) \stackrel{\text{def}}{=} \{f \mid f : D \rightarrow E \text{ is a } \textit{continuous} \text{ function}\}$$

and partial order: $f \sqsubseteq f' \stackrel{\text{def}}{\iff} \forall d \in D. f(d) \sqsubseteq_E f'(d)$.

- A derived rule:

$$\frac{f \sqsubseteq_{(D \rightarrow E)} g \quad x \sqsubseteq_D y}{f(x) \sqsubseteq g(y)}$$

Lubs of chains are calculated ‘argumentwise’ (using lubs in E):

$$\bigsqcup_{n \geq 0} f_n = \lambda d \in D. \bigsqcup_{n \geq 0} f_n(d) .$$

- A derived rule:

$$\frac{}{(\bigsqcup_n f_n)(\bigsqcup_m x_m) = \bigsqcup_k f_k(x_k)}$$

If E is a domain, then so is $D \rightarrow E$ and $\perp_{D \rightarrow E}(d) = \perp_E$, all $d \in D$.

Slide 36

Proof of Slide 35. We should show that the lub of a chain of functions, $\bigsqcup_{n \geq 0} f_n$, is continuous. The proof uses the ‘interchange law’ of Slide 27]. Given a chain in D ,

$$\begin{aligned} (\bigsqcup_{n \geq 0} f_n)((\bigsqcup_{m \geq 0} d_m)) &= \bigsqcup_{n \geq 0} (f_n(\bigsqcup_{m \geq 0} d_m)) && \text{definition of } \bigsqcup_{n \geq 0} f_n \\ &= \bigsqcup_{n \geq 0} (\bigsqcup_{m \geq 0} f_n(d_m)) && \text{continuity of each } f_n \\ &= \bigsqcup_{m \geq 0} (\bigsqcup_{n \geq 0} f_n(d_m)) && \text{interchange law} \\ &= \bigsqcup_{m \geq 0} ((\bigsqcup_{n \geq 0} f_n)(d_m)) && \text{definition of } \bigsqcup_{n \geq 0} f_n. \end{aligned}$$

□

Proposition 3.3.1 (Evaluation and ‘Currying’). *Given cpo’s D and E , the function*

$$ev : (D \rightarrow E) \times D \rightarrow E$$

$$ev(f, d) \stackrel{\text{def}}{=} f(d)$$

is continuous. Given any continuous function $f : D' \times D \rightarrow E$ (with D' a cpo), for each $d' \in D'$ the function $d \in D \mapsto f(d', d)$ is continuous and hence determines an element of the function cpo $D \rightarrow E$ that we denote by $cur(f)(d')$. Then

$$\begin{aligned} cur(f) : D' &\rightarrow (D \rightarrow E) \\ cur(f)(d') &\stackrel{\text{def}}{=} \lambda d \in D. f(d', d) \end{aligned}$$

is a continuous function.¹

Proof. For continuity of ev note that

$$\begin{aligned} ev\left(\bigsqcup_{n \geq 0} (f_n, d_n)\right) &= ev\left(\bigsqcup_{i \geq 0} f_i, \bigsqcup_{j \geq 0} d_j\right) && \text{lubs in products are componenwise} \\ &= \left(\bigsqcup_{i \geq 0} f_i\right) \left(\bigsqcup_{j \geq 0} d_j\right) && \text{by definition of } ev \\ &= \bigsqcup_{i \geq 0} f_i \left(\bigsqcup_{j \geq 0} d_j\right) && \text{lubs in function cpo's are argumentwise} \\ &= \bigsqcup_{i \geq 0} \bigsqcup_{j \geq 0} f_i(d_j) && \text{by continuity of each } f_i \\ &= \bigsqcup_{n \geq 0} f_n(d_n) && \text{by the Lemma on Slide 27} \\ &= \bigsqcup_{n \geq 0} ev(f_n, d_n) && \text{by definition of } ev. \end{aligned}$$

The continuity of each $cur(f)(d')$ and then of $cur(f)$ follows immediately from the fact that lubs of chains in $D_1 \times D_2$ can be calculated componentwise. \square

¹This ‘Curried’ version of f is named in honour of the logician H. B. Curry, a pioneer of combinatory logic and lambda calculus.

Continuity of composition

For cpo's D, E, F , the composition function

$$\circ : ((E \rightarrow F) \times (D \rightarrow E)) \longrightarrow (D \rightarrow F)$$

defined by setting, for all $f \in (D \rightarrow E)$ and $g \in (E \rightarrow F)$,

$$g \circ f = \lambda d \in D. g(f(d))$$

is continuous.

Slide 37

Continuity of the fixpoint operator

Let D be a domain.

By Tarski's Fixed Point Theorem we know that each continuous function $f \in (D \rightarrow D)$ possesses a least fixed point, $fix(f) \in D$.

Proposition. *The function*

$$fix : (D \rightarrow D) \rightarrow D$$

is continuous.

Slide 38

Proof of the Proposition on Slide 38. We must first prove that $fix : (D \rightarrow D) \rightarrow D$ is a monotone function. Suppose $f_1 \sqsubseteq f_2$ in the function domain $D \rightarrow D$. We have to prove $fix(f_1) \sqsubseteq fix(f_2)$. But:

$$\begin{aligned} f_1(fix(f_2)) &\sqsubseteq f_2(fix(f_2)) && \text{since } f_1 \sqsubseteq f_2 \\ &\sqsubseteq fix(f_2) && \text{by (lfp1) for } fix(f_2). \end{aligned}$$

So $fix(f_2)$ is a pre-fixed point for f_1 and hence by (lfp2) (for $fix(f_1)$) we have $fix(f_1) \sqsubseteq fix(f_2)$, as required.

Turning now to the preservation of lubs of chains, suppose $f_0 \sqsubseteq f_1 \sqsubseteq f_2 \sqsubseteq \dots$ in $D \rightarrow D$. Recalling Remark 2.3.7, we just have to prove that

$$fix\left(\bigsqcup_{n \geq 0} f_n\right) \sqsubseteq \bigsqcup_{n \geq 0} fix(f_n)$$

and by the property (lfp2) of least pre-fixed points (see Slide 19), for this it suffices to show that $\bigsqcup_{n \geq 0} fix(f_n)$ is a pre-fixed point for the function $\bigsqcup_{n \geq 0} f_n$. This is the case because:

$$\begin{aligned} \left(\bigsqcup_{m \geq 0} f_m\right)\left(\bigsqcup_{n \geq 0} fix(f_n)\right) &= \bigsqcup_{m \geq 0} f_m\left(\bigsqcup_{n \geq 0} fix(f_n)\right) && \text{function lubs are argumentwise} \\ &= \bigsqcup_{m \geq 0} \bigsqcup_{n \geq 0} f_m(fix(f_n)) && \text{by continuity of each } f_m \\ &= \bigsqcup_{k \geq 0} f_k(fix(f_k)) && \text{by the Lemma on Slide 27} \\ &\sqsubseteq \bigsqcup_{k \geq 0} fix(f_k) && \text{by (lfp1) for each } f_k. \end{aligned}$$

□

3.4 Exercises

Exercise 3.4.1. Verify that the constructions given on Slide 32, in Definition 3.2.3, and on Slides 35 and 31 do give cpo's and domains (i.e. that properties (i), (ii) and (ii) mentioned at the start of this section do hold in each case). Give the proofs of Propositions 3.1.1 and 3.2.2.

Exercise 3.4.2. Let X and Y be sets and X_\perp and Y_\perp the corresponding flat domains, as on Slide 31. Show that a function $f : X_\perp \rightarrow Y_\perp$ is continuous if and only if one of (a) or (b) holds:

- (a) f is strict, i.e. $f(\perp) = \perp$.
- (b) f is constant, i.e. $\forall x \in X. f(x) = f(\perp)$.

Exercise 3.4.3. Let $\{\top\}$ be a one-element set and $\{\top\}_\perp$ the corresponding flat domain. Let Ω be the domain of ‘vertical natural numbers’, pictured in Figure 1. Show that the function domain $(\Omega \rightarrow \{\top\}_\perp)$ is in bijection with Ω .

Exercise 3.4.4. Prove the Proposition on Slide 37.

4 Scott Induction

4.1 Chain-closed and admissible subsets

In Section 2 we saw that the least fixed point of a continuous function $f : D \rightarrow D$ on a domain D can be expressed as the lub of the chain obtained by repeatedly applying f starting with the least element \perp of D : $\text{fix}(f) = \bigsqcup_{n \geq 0} f^n(\perp)$ (cf. Slide 29). This construction allows one to prove properties of $\text{fix}(f)$ by using Mathematical Induction for n to show that each $f^n(\perp)$ has the property, *provided* the property in question satisfies the condition shown on Slide 39. It is convenient to package up this use of Mathematical Induction in a way that hides the explicit construction of $\text{fix}(f)$ as the lub of a chain. This is done on Slide 40. To see the validity of the statement on that slide, note that $f^0(\perp) = \perp \in S$ by the **Base case**; and $f^n(\perp) \in S$ implies $f^{n+1}(\perp) = f(f^n(\perp)) \in S$ by the **Induction step**. Hence by induction on n , we have $\forall n \geq 0. f^n(\perp) \in S$. Therefore by the chain-closedness of S , $\text{fix}(f) = \bigsqcup_{n \geq 0} f^n(\perp) \in S$, as required.

Chain-closed and admissible subsets

Let D be a cpo. A subset $S \subseteq D$ is called *chain-closed* iff for all chains $d_0 \sqsubseteq d_1 \sqsubseteq d_2 \sqsubseteq \dots$ in D

$$(\forall n \geq 0. d_n \in S) \Rightarrow \left(\bigsqcup_{n \geq 0} d_n \right) \in S$$

If D is a domain, $S \subseteq D$ is called *admissible* iff it is a chain-closed subset of D and $\perp \in S$.

A property $\Phi(d)$ of elements $d \in D$ is called *chain-closed* (resp. *admissible*) iff $\{d \in D \mid \Phi(d)\}$ is a *chain-closed* (resp. *admissible*) subset of D .

Slide 39

Note. The terms *inclusive*, or *inductive*, are often used as synonyms of ‘chain-closed’.

Example 4.1.1. Consider the domain Ω of ‘vertical natural numbers’ pictured in Figure 1. Then

- any *finite* subset of Ω is chain-closed;

- $\{0, 2, 4, 6, \dots\}$ is not a chain-closed subset of Ω ;
- $\{0, 2, 4, 6, \dots\} \cup \{\omega\}$ is a chain-closed (indeed, is an admissible) subset of Ω .

Scott's Fixed Point Induction Principle

Let $f : D \rightarrow D$ be a continuous function on a domain D .

For any admissible subset $S \subseteq D$, to prove that the least fixed point of f is in S , i.e. that

$$fix(f) \in S ,$$

it suffices to prove

$$\forall d \in D (d \in S \Rightarrow f(d) \in S) .$$

Slide 40

The difficulty with applying Scott's Fixed Point Induction Principle in any particular case usually lies in identifying an appropriate admissible subset S ; i.e. in finding a suitably strong 'induction hypothesis'.

4.2 Examples

Example 4.2.1. Suppose that D is a domain and that $f : (D \times (D \times D)) \rightarrow D$ is a continuous function. Let $g : (D \times D) \rightarrow (D \times D)$ be the continuous function defined by

$$g(d_1, d_2) \stackrel{\text{def}}{=} (f(d_1, (d_1, d_2)), f(d_1, (d_2, d_2))) \quad (d_1, d_2 \in D).$$

Then $u_1 = u_2$, where $(u_1, u_2) \stackrel{\text{def}}{=} fix(g)$. (Note that g is continuous because we can express it in terms of composition, projections and pairing and hence apply Proposition 3.2.1 and Slide 37: $g = \langle f \circ \langle \pi_1, \langle \pi_1, \pi_2 \rangle \rangle, f \circ \langle \pi_1, \langle \pi_2, \pi_2 \rangle \rangle \rangle$.)

Proof. We have to show that $fix(g) \in \Delta$ where

$$\Delta \stackrel{\text{def}}{=} \{(d_1, d_2) \in D \times D \mid d_1 = d_2\}.$$

It is not hard to see that Δ is an admissible subset of the product domain $D \times D$. So by Scott's Fixed Point Induction Principle, we just have to check that

$$\forall (d_1, d_2) \in D \times D ((d_1, d_2) \in \Delta \Rightarrow g(d_1, d_2) \in \Delta)$$

or equivalently, that

$$\forall (d_1, d_2) \in D \times D (d_1 = d_2 \Rightarrow f(d_1, d_1, d_2) = f(d_1, d_2, d_2)),$$

which is clearly true. \square

The next example shows that Scott's Induction Principle can be useful for proving (the denotational version of) *partial correctness* assertions about programs, i.e. assertions of the form 'if the program terminates, then such-and-such a property holds of the results'. By contrast, a *total correctness* assertion would be 'the program does terminate and such-and-such a property holds of the results'. Because Scott Induction can only be applied for properties Φ for which $\Phi(\perp)$ holds, it is not so useful for proving total correctness.

Example 4.2.2. Let $f : D \rightarrow D$ be the continuous function defined on Slide 12 whose least fixed point is the denotation of the command

$$\text{while } X > 0 \text{ do } (Y := X * Y ; X := X - 1).$$

We will use Scott Induction to prove

(7)

$$\forall x, y \geq 0.$$

$$\text{fix}(f)[X \mapsto x, Y \mapsto y] \downarrow \Rightarrow \text{fix}(f)[X \mapsto x, Y \mapsto y] = [X \mapsto 0, Y \mapsto (!x) * y]$$

where for $w \in D = ((\mathbb{Z} \times \mathbb{Z}) \rightarrow (\mathbb{Z} \times \mathbb{Z}))$ we write $w(x, y) \downarrow$ to mean 'the partial function w is defined at the state $[X \mapsto x, Y \mapsto y]$ '.

Proof. Let

$$S \stackrel{\text{def}}{=} \left\{ w \in D \left| \begin{array}{l} \forall x, y \geq 0. \\ w[X \mapsto x, Y \mapsto y] \downarrow \\ \Rightarrow w[X \mapsto x, Y \mapsto y] = [X \mapsto 0, Y \mapsto (!x) * y] \end{array} \right. \right\}.$$

It is not hard to see that S is admissible. Therefore, to prove (7), by Scott Induction it suffices to check that $w \in S$ implies $f(w) \in S$, for all $w \in D$. So suppose $w \in S$, that $x, y \geq 0$, and that $f(w)[X \mapsto x, Y \mapsto y] \downarrow$. We have to show that $f(w)[X \mapsto x, Y \mapsto y] = [X \mapsto 0, Y \mapsto (!x) * y]$. We consider the two cases $x = 0$ and $x > 0$ separately.

If $x = 0$, then by definition of f (see Slide 12)

$$\begin{aligned} f(w)[X \mapsto x, Y \mapsto y] &= [X \mapsto x, Y \mapsto y] &= [X \mapsto 0, Y \mapsto y] \\ &= [X \mapsto 0, Y \mapsto 1 * y] &= [X \mapsto 0, Y \mapsto (!0) * y] \\ &= [X \mapsto 0, Y \mapsto (!x) * y]. \end{aligned}$$

On the other hand, if $x > 0$, then by definition of f

$$w[X \mapsto x - 1, Y \mapsto x * y] = f(w)[X \mapsto x, Y \mapsto y] \downarrow \quad (\text{by assumption})$$

and then since $w \in S$ and $x - 1, x * y \geq 0$, we must have

$$w[X \mapsto x - 1, Y \mapsto x * y] = [X \mapsto 0, Y \mapsto !(x - 1) * (x * y)]$$

and hence once again

$$\begin{aligned} f(w)[X \mapsto x, Y \mapsto y] &= w[X \mapsto x - 1, Y \mapsto x * y] \\ &= [X \mapsto 0, Y \mapsto !(x - 1) * (x * y)] \\ &= [X \mapsto 0, Y \mapsto (!x) * y] . \end{aligned}$$

□

4.3 Building chain-closed subsets

The power of Scott induction depends on having a good stock of chain-closed subsets. Fortunately we are able to ensure that a good many subsets are chain-closed by virtue of the way in which they are built up.

4.3.1 Basic relations

Let D be a cpo. The subsets

$$\{(x, y) \in D \times D \mid x \sqsubseteq y\} \text{ and } \{(x, y) \in D \times D \mid x = y\}$$

of $D \times D$ are chain-closed (Why?). The properties (or predicates) $x \sqsubseteq y$ and $x = y$ on $D \times D$ determine chain-closed sets.

Example (I): Least pre-fixed point property

Let D be a domain and let $f : D \rightarrow D$ be a continuous function.

$$\forall d \in D. f(d) \sqsubseteq d \implies \text{fix}(f) \sqsubseteq d$$

Proof by Scott induction.

Let $d \in D$ be a pre-fixed point of f . Then,

$$\begin{aligned} x \in \downarrow(d) &\implies x \sqsubseteq d \\ &\implies f(x) \sqsubseteq f(d) \\ &\implies f(x) \sqsubseteq d \\ &\implies f(x) \in \downarrow(d) \end{aligned}$$

Hence,

$$\text{fix}(f) \in \downarrow(d) .$$

Slide 41

4.3.2 Inverse image and substitution

Let $f : D \rightarrow E$ be a continuous function between cpos D and E . Suppose S is a chain-closed subset of E . Then the inverse image

$$f^{-1}S = \{x \in D \mid f(x) \in S\}$$

is an chain-closed subset of D (Why?).

Suppose the subset S is defined by the property P on E i.e.

$$S = \{y \in E \mid P(y)\}.$$

Then

$$f^{-1}S = \{x \in D \mid P(f(x))\}.$$

So, if a property $P(y)$ on E determines a chain-closed subset of E and $f : D \rightarrow E$ is a continuous function, then the property $P(f(x))$ on D determines a chain-closed subset of D .

Example (II)

Let D be a domain and let $f, g : D \rightarrow D$ be continuous functions such that $f \circ g \sqsubseteq g \circ f$. Then,

$$f(\perp) \sqsubseteq g(\perp) \implies \text{fix}(f) \sqsubseteq \text{fix}(g) .$$

Proof by Scott induction.

Consider the admissible property $\Phi(x) \equiv (f(x) \sqsubseteq g(x))$ of D .

Since

$$f(x) \sqsubseteq g(x) \implies g(f(x)) \sqsubseteq g(g(x)) \implies f(g(x)) \sqsubseteq g(g(x))$$

we have that

$$f(\text{fix}(g)) \sqsubseteq g(\text{fix}(g)) .$$

Slide 42

4.3.3 Logical operations

Let D be a cpo. Let $S \subseteq D$ and $T \subseteq D$ be chain-closed subsets of D . Then

$$S \cup T \text{ and } S \cap T$$

are chain-closed subsets (Why?). In terms of properties, if $P(x)$ and $Q(x)$ determine chain-closed subsets of D , then so do

$$P(x) \text{ or } Q(x), \quad P(x) \ \& \ Q(x).$$

If $S_i, i \in I$, is a family of chain-closed subsets of D indexed by a set I , then $\bigcap_{i \in I} S_i$ is a chain-closed subset of D (Why?).

Consequently, if a property $P(x, y)$ determines a chain-closed subset of $D \times E$, then the property $\forall x \in D. P(x, y)$ determines a chain-closed subset of E . This is because

$$\begin{aligned} \{y \in E \mid \forall x \in D. P(x, y)\} &= \bigcap_{d \in D} \{y \in E \mid P(d, y)\} \\ &= \bigcap_{d \in D} f_d^{-1}\{(x, y) \in D \times E \mid P(x, y)\} \end{aligned}$$

where $f_d : E \rightarrow D \times E$ is the continuous function defined as $f_d(y) = (d, y)$ for every $d \in D$.

In fact, any property built-up as a universal quantification over several variables of conjunctions and disjunctions of basic properties of the form $f(x_1, \dots, x_k) \sqsubseteq g(x_1, \dots, x_l)$ or $f(x_1, \dots, x_k) = g(x_1, \dots, x_l)$, where f and g are continuous, will determine a chain-closed subset of the product cpo appropriate to the non-quantified variables.

Note, however, that infinite unions of chain-closed subsets need not be chain-closed; finite subsets are always chain complete but arbitrary unions of them need not be. Accordingly, we cannot in general build chain-closed subsets with existential quantifications.

4.4 Exercises

Exercise 4.4.1. Answer all the “Why?”s above in the building of chain-closed subsets.

Exercise 4.4.2. Give an example of a subset $S \subseteq D \times D'$ of a product cpo that is not chain-closed, but which satisfies both of the following:

- (a) for all $d \in D$, $\{d' \mid (d, d') \in S\}$ is a chain-closed subset of D' ; and
- (b) for all $d' \in D'$, $\{d \mid (d, d') \in S\}$ is a chain-closed subset of D .

[Hint: consider $D = D' = \Omega$, the cpo in Figure 1.]

(Compare this with the property of continuous functions given on Slide 33.)

5 PCF

The language PCF (‘Programming Computable Functions’) is a simple functional programming language that has been used extensively as an example language in the development of the theory of both denotational and operational semantics (and the relationship between the two). Its syntax was introduced by Dana Scott *circa* 1969 as part of a ‘Logic of Computable Functions’¹ and was studied as a programming language in a highly influential paper by Plotkin (1977).

In this section we describe the syntax and operational semantics of the particular version of PCF we use in these notes. In Section 6 we will see how to give it a denotational semantics using domains and continuous function.

5.1 Terms and types

The *types*, *expressions*, and *terms* of the PCF language are defined on Slide 43.

PCF syntax

Types

$$\tau ::= \mathit{nat} \mid \mathit{bool} \mid \tau \rightarrow \tau$$

Expressions

$$M ::= \mathbf{0} \mid \mathbf{succ}(M) \mid \mathbf{pred}(M) \\ \mid \mathbf{true} \mid \mathbf{false} \mid \mathbf{zero}(M) \\ \mid x \mid \mathbf{if} \ M \ \mathbf{then} \ M \ \mathbf{else} \ M \\ \mid \mathbf{fn} \ x : \tau . M \mid M M \mid \mathbf{fix}(M)$$

where $x \in \mathbb{V}$, an infinite set of *variables*.

Technicality: We identify expressions up to α -conversion of bound variables (created by the **fn** expression-former): by definition a PCF *term* is an α -equivalence class of expressions.

Slide 43

The intended meaning of the various syntactic forms is as follows.

- *nat* is the type of the natural numbers, 0, 1, 2, 3, In PCF these are generated from 0 by repeated application of the successor operation, **succ**(–), whose intended meaning is to add 1 to its argument. The predecessor operation **pred**(–) subtracts 1 from strictly positive natural numbers (and is undefined at 0).

¹This logic was the stimulus for the development of the ML language and LCF system for machine-assisted proofs by Milner, Gordon *et al*—see Paulson 1987; Scott’s original work was eventually published as Scott 1993.

- *bool* is the type of booleans, *true* and *false*. The operation $\mathbf{zero}(-)$ tests whether its argument is zero or strictly positive and returns **true** or **false** accordingly. The *conditional* expression **if** M_1 **then** M_2 **else** M_3 behaves like either M_2 or M_3 depending upon whether M_1 evaluates to **true** or **false** respectively.
- A PCF variable, x , stands for an unknown expression. PCF is a pure functional language—there is no state that changes during expression evaluation and in particular variables are ‘identifiers’ standing for a fixed expression, rather than ‘program variables’ whose contents may get mutated during evaluation.
- $\tau \rightarrow \tau'$ is the type of (partial) functions taking a single argument of type τ and (possibly) returning a result of type τ' . $\mathbf{fn} x : \tau . M$ is the notation we will use for function abstraction (i.e. lambda abstraction) in PCF; note that the type τ of the abstracted variable x is given explicitly. The application of function M_1 to argument M_2 is indicated by $M_1 M_2$. As usual, the scope of a function abstraction extends as far to the right of the dot as possible and function application associates to the left (i.e. $M_1 M_2 M_3$ means $(M_1 M_2) M_3$, not $M_1 (M_2 M_3)$).
- The expression $\mathbf{fix}(M)$ indicates an element x *recursively defined* by $x = M x$. The lambda calculus equivalent is $Y M$, where Y is a suitable fixpoint combinator.

5.2 Free variables, bound variables, and substitution

PCF contains one variable-binding form: free occurrences of x in M become bound in $\mathbf{fn} x : \tau . M$. The finite set of *free variables* of an expression M , $fv(M)$, is defined by induction on its structure, as follows:

$$fv(\mathbf{0}) = fv(\mathbf{true}) = fv(\mathbf{false}) \stackrel{\text{def}}{=} \emptyset$$

$$fv(\mathbf{succ}(M)) = fv(\mathbf{pred}(M)) = fv(\mathbf{zero}(M)) = fv(\mathbf{fix}(M)) \stackrel{\text{def}}{=} fv(M)$$

$$fv(\mathbf{if} M \mathbf{then} M' \mathbf{else} M'') \stackrel{\text{def}}{=} fv(M) \cup fv(M') \cup fv(M'')$$

$$fv(M M') \stackrel{\text{def}}{=} fv(M) \cup fv(M')$$

$$fv(x) \stackrel{\text{def}}{=} \{x\}$$

$$fv(\mathbf{fn} x : \tau . M) \stackrel{\text{def}}{=} \{x' \in fv(M) \mid x' \neq x\}.$$

One says that M is *closed* if $fv(M) = \emptyset$ and *open* otherwise.

As indicated on Slide 43, we will identify α -convertible PCF expressions, i.e. ones that differ only up to the names of their bound variables. Thus by definition, a PCF *term* is an equivalence class of PCF expressions for the equivalence relation of α -conversion. However, we will always refer to a term via some representative expression, usually choosing one whose bound variables are all distinct from each other and from any other variables in the context in which the term is being used. The operation of *substituting a term M for all free occurrences of a variable x in a term M'* will be written

$$M'[M/x].$$

The operation is carried out by textual substitution of an expression representing M for free occurrences of x in an expression representing M' whose binding variables are distinct from the free variables in M (thereby avoiding ‘capture’ of free variables in M by binders in M').

5.3 Typing

PCF is a typed language: types are assigned to terms via the relation shown on Slide 44 whose intended meaning is “if each $x \in \text{dom}(\Gamma)$ has type $\Gamma(x)$, then M has type τ ”.

PCF typing relation, $\Gamma \vdash M : \tau$

- Γ is a *type environment*, i.e. a finite partial function mapping variables to types (whose domain of definition is denoted $\text{dom}(\Gamma)$)
- M is a term
- τ is a *type*.

Relation is inductively defined by the axioms and rules in Figure 2.

Notation:

$M : \tau$ means M is closed and $\emptyset \vdash M : \tau$ holds.

$\text{PCF}_\tau \stackrel{\text{def}}{=} \{M \mid M : \tau\}$.

(<i>:0</i>)	$\Gamma \vdash \mathbf{0} : nat$
(<i>:succ</i>)	$\frac{\Gamma \vdash M : nat}{\Gamma \vdash \mathbf{succ}(M) : nat}$
(<i>:pred</i>)	$\frac{\Gamma \vdash M : nat}{\Gamma \vdash \mathbf{pred}(M) : nat}$
(<i>:zero</i>)	$\frac{\Gamma \vdash M : nat}{\Gamma \vdash \mathbf{zero}(M) : bool}$
(<i>:bool</i>)	$\Gamma \vdash b : bool \quad (b = true, false)$
(<i>:if</i>)	$\frac{\Gamma \vdash M_1 : bool \quad \Gamma \vdash M_2 : \tau \quad \Gamma \vdash M_3 : \tau}{\Gamma \vdash \mathbf{if} M_1 \mathbf{then} M_2 \mathbf{else} M_3 : \tau}$
(<i>:var</i>)	$\Gamma \vdash x : \tau \quad \mathbf{if} x \in dom(\Gamma) \ \& \ \Gamma(x) = \tau$
(<i>:fn</i>)	$\frac{\Gamma[x \mapsto \tau] \vdash M : \tau'}{\Gamma \vdash \mathbf{fn} x : \tau . M : \tau \rightarrow \tau'} \quad \mathbf{if} x \notin dom(\Gamma)$
(<i>:app</i>)	$\frac{\Gamma \vdash M_1 : \tau \rightarrow \tau' \quad \Gamma \vdash M_2 : \tau}{\Gamma \vdash M_1 M_2 : \tau'}$
(<i>:fix</i>)	$\frac{\Gamma \vdash M : \tau \rightarrow \tau}{\Gamma \vdash \mathbf{fix}(M) : \tau}$

In rule (*:fn*), $\Gamma[x \mapsto \tau]$ denotes the type environment mapping x to τ and otherwise acting like Γ .

Figure 2: Axioms and rules for PCF typing relation

Proposition 5.3.1.

- (i) If $\Gamma \vdash M : \tau$ holds, then $fv(M) \subseteq dom(\Gamma)$. If both $\Gamma \vdash M : \tau$ and $\Gamma \vdash M : \tau'$ hold, then $\tau = \tau'$. In particular a closed term has at most one type.
- (ii) If $\Gamma \vdash M : \tau$ and $\Gamma[x \mapsto \tau] \vdash M' : \tau'$ both hold, then so does $\Gamma \vdash M'[M/x] : \tau'$.

Proof. These properties of the inductively defined typing relation are easily proved by rule induction. The fact that a term has at most one type for a given assignment of types to its free variables relies upon the fact that types of bound variables are given explicitly in function abstractions. \square

Example 5.3.2 (Partial recursive functions in PCF). Although the PCF syntax is rather terse, the combination of increment, decrement, test for zero, conditionals, function abstraction and application, and fixpoint recursion makes it Turing expressive—in the sense that all partial recursive functions¹ can be coded. For example, recall that the partial function $h : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$ defined by *primitive recursion* from $f : \mathbb{N} \rightarrow \mathbb{N}$ and $g : \mathbb{N} \times \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$ satisfies that for all $x, y \in \mathbb{N}$

$$\begin{cases} h(x, 0) & = f(x) \\ h(x, y + 1) & = g(x, y, h(x, y)). \end{cases}$$

Thus if f has been coded in PCF by a term $F : nat \rightarrow nat$ and g by a term $G : nat \rightarrow (nat \rightarrow (nat \rightarrow nat))$, then h can be coded by

$$H \stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} h : nat \rightarrow (nat \rightarrow nat) . \mathbf{fn} x : nat . \mathbf{fn} y : nat . \\ \mathbf{if} \mathbf{zero}(y) \mathbf{then} F x \mathbf{else} G x (\mathbf{pred} y) (h x (\mathbf{pred} y))).$$

Apart from primitive recursion, the other construction needed for defining partial recursive functions is *minimisation*. For example, the partial function $m : \mathbb{N} \rightarrow \mathbb{N}$ defined from $k : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$ by minimisation satisfies that for all $x \in \mathbb{N}$

$$m(x) = \text{least } y \geq 0 \text{ such that } k(x, y) = 0 \text{ and} \\ \forall z. 0 \leq z < y \Rightarrow k(x, z) > 0.$$

This can also be expressed using fixpoints, although not so easily as in the case of primitive recursion. For if k has been coded in PCF by a term $K : nat \rightarrow (nat \rightarrow nat)$, then in fact m can be coded as $\mathbf{fn} x : nat . M' x 0$ where

$$M' \stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} m' : nat \rightarrow (nat \rightarrow nat) . \mathbf{fn} x : nat . \mathbf{fn} y : nat . \\ \mathbf{if} \mathbf{zero}(K x y) \mathbf{then} y \mathbf{else} m' x (\mathbf{succ} y)).$$

¹See the Part IB course on **Computation Theory**.

5.4 Evaluation

We give the operational semantics of PCF in terms of an inductively defined relation of evaluation whose form is shown on Slide 45. As indicated there, the results of evaluation are PCF terms of a particular form, called *values* (and sometimes also called ‘canonical forms’). The only values of type *bool* are **true** and **false**. The values of type *nat* are unary representations of natural numbers, $\mathbf{succ}^n(\mathbf{0})$ ($n \in \mathbb{N}$), where

$$\begin{cases} \mathbf{succ}^0(\mathbf{0}) & \stackrel{\text{def}}{=} \mathbf{0} \\ \mathbf{succ}^{n+1}(\mathbf{0}) & \stackrel{\text{def}}{=} \mathbf{succ}(\mathbf{succ}^n(\mathbf{0})). \end{cases}$$

Values at function types, being function abstractions $\mathbf{fn} x : \tau . M$, are more ‘intensional’ than those at the ground data types, since the body M is an unevaluated PCF term. The axioms and rules for generating the evaluation relation are given in Figure 3.

PCF evaluation relation

takes the form

$$M \Downarrow_{\tau} V$$

where

- τ is a PCF type
- $M, V \in \text{PCF}_{\tau}$ are closed PCF terms of type τ
- V is a *value*,
 $V ::= \mathbf{0} \mid \mathbf{succ}(V) \mid \mathbf{true} \mid \mathbf{false} \mid \mathbf{fn} x : \tau . M.$

The evaluation relation is inductively defined by the axioms and rules in Figure 3.

Slide 45

Proposition 5.4.1. *Evaluation in PCF is deterministic: if both $M \Downarrow_{\tau} V$ and $M \Downarrow_{\tau} V'$ hold, then $V = V'$.*

Proof. By rule induction: one shows that

$$\{(M, \tau, V) \mid M \Downarrow_{\tau} V \ \& \ \forall V' (M \Downarrow_{\tau} V' \Rightarrow V = V')\}$$

is closed under the axioms and rules defining \Downarrow . We omit the details. □

(\Downarrow_{val})	$V \Downarrow_{\tau} V$ (V a value of type τ)
(\Downarrow_{succ})	$\frac{M \Downarrow_{\text{nat}} V}{\mathbf{succ}(M) \Downarrow_{\text{nat}} \mathbf{succ}(V)}$
(\Downarrow_{pred})	$\frac{M \Downarrow_{\text{nat}} \mathbf{succ}(V)}{\mathbf{pred}(M) \Downarrow_{\text{nat}} V}$
($\Downarrow_{\text{zero1}}$)	$\frac{M \Downarrow_{\text{nat}} \mathbf{0}}{\mathbf{zero}(M) \Downarrow_{\text{bool}} \mathbf{true}}$
($\Downarrow_{\text{zero2}}$)	$\frac{M \Downarrow_{\text{nat}} \mathbf{succ}(V)}{\mathbf{zero}(M) \Downarrow_{\text{bool}} \mathbf{false}}$
(\Downarrow_{if1})	$\frac{M_1 \Downarrow_{\text{bool}} \mathbf{true} \quad M_2 \Downarrow_{\tau} V}{\mathbf{if } M_1 \mathbf{ then } M_2 \mathbf{ else } M_3 \Downarrow_{\tau} V}$
(\Downarrow_{if2})	$\frac{M_1 \Downarrow_{\text{bool}} \mathbf{false} \quad M_3 \Downarrow_{\tau} V}{\mathbf{if } M_1 \mathbf{ then } M_2 \mathbf{ else } M_3 \Downarrow_{\tau} V}$
(\Downarrow_{cbn})	$\frac{M_1 \Downarrow_{\tau \rightarrow \tau'} \mathbf{fn } x : \tau . M'_1 \quad M'_1[M_2/x] \Downarrow_{\tau'} V}{M_1 M_2 \Downarrow_{\tau'} V}$
(\Downarrow_{fix})	$\frac{M \mathbf{fix}(M) \Downarrow_{\tau} V}{\mathbf{fix}(M) \Downarrow_{\tau} V}$

Figure 3: Axioms and rules for PCF evaluation

Example 5.4.2. The proposition shows that every closed typeable term evaluates to at most one value. Of course there are some typeable terms that do not evaluate to anything. We write $M \Downarrow_\tau$ iff $M : \tau$ and $\exists V. M \Downarrow_\tau V$. Then for example

$$\Omega_\tau \stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} x : \tau . x)$$

satisfies $\Omega_\tau \not\Downarrow_\tau$. (For if for some V there were a proof of $\mathbf{fix}(\mathbf{fn} x : \tau . x) \Downarrow_\tau V$, choose one of minimal height. This proof, call it \mathcal{P} , must look like

$$\frac{\frac{\frac{}{\mathbf{fn} x : \tau . x \Downarrow \mathbf{fn} x : \tau . x} (\Downarrow_{\text{val}}) \quad \mathbf{fix}(\mathbf{fn} x : \tau . x) \Downarrow V \quad \mathcal{P}'}{(\mathbf{fn} x : \tau . x) (\mathbf{fix}(\mathbf{fn} x : \tau . x)) \Downarrow V} (\Downarrow_{\text{cbn}})}{\mathbf{fix}(\mathbf{fn} x : \tau . x) \Downarrow V} (\Downarrow_{\text{fix}})}$$

where \mathcal{P}' is a strictly shorter proof of $\mathbf{fix}(\mathbf{fn} x : \tau . x) \Downarrow_\tau V$, which contradicts the minimality of \mathcal{P} .)

Remark 5.4.3. PCF evaluation can be defined in terms of a ‘one-step’ transition relation. Let the relation $M \rightarrow_\tau M'$ (for $M, M' \in \text{PCF}_\tau$) be inductively defined by the axioms and rules in Figure 4. Then one can show that for all τ and $M, V \in \text{PCF}_\tau$ with V a value

$$M \Downarrow_\tau V \Leftrightarrow M(\rightarrow_\tau)^* V$$

where $(\rightarrow_\tau)^*$ denotes the reflexive-transitive closure of the relation \rightarrow_τ .

$$\begin{array}{c}
\frac{M \rightarrow_{nat} M'}{\mathbf{op}(M) \rightarrow_{\tau} \mathbf{op}(M')} \quad \left(\begin{array}{l} \text{where } \mathbf{op} = \mathbf{succ}, \mathbf{pred} \ \& \ \tau = nat, \\ \text{or } \mathbf{op} = \mathbf{zero} \ \& \ \tau = bool \end{array} \right) \\
\mathbf{pred}(\mathbf{succ}(V)) \rightarrow_{nat} V \quad (V \text{ a value of type } nat) \\
\mathbf{zero}(\mathbf{0}) \rightarrow_{bool} \mathbf{true} \\
\mathbf{zero}(\mathbf{succ}(V)) \rightarrow_{bool} \mathbf{false} \quad (V \text{ a value of type } nat) \\
\frac{M_1 \rightarrow_{bool} M'_1}{\mathbf{if } M_1 \mathbf{ then } M_2 \mathbf{ else } M_3 \rightarrow_{\tau} \mathbf{if } M'_1 \mathbf{ then } M_2 \mathbf{ else } M_3} \\
\mathbf{if } \mathbf{true} \mathbf{ then } M_1 \mathbf{ else } M_2 \rightarrow_{\tau} M_1 \\
\mathbf{if } \mathbf{false} \mathbf{ then } M_1 \mathbf{ else } M_2 \rightarrow_{\tau} M_2 \\
\frac{M_1 \rightarrow_{\tau \rightarrow \tau'} M'_1}{M_1 M_2 \rightarrow_{\tau'} M'_1 M_2} \\
(\mathbf{fn } x : \tau . M_1) M_2 \rightarrow_{\tau'} M_1[M_2/x] \\
\mathbf{fix}(M) \rightarrow_{\tau} M \mathbf{fix}(M)
\end{array}$$

Figure 4: Axioms and rules for PCF transition relation

5.5 Contextual equivalence

Contextual equivalence

Two phrases of a programming language are *contextually equivalent* if any occurrences of the first phrase in a complete program can be replaced by the second phrase without affecting the observable results of executing the program.

Slide 46

Slide 46 recalls (from the CST Part IB course on **Semantics of Programming Languages**) the general notion of contextual equivalence of phrases in a programming language. It is really a family of notions, parameterised by the particular choices one takes for what constitutes a ‘program’ in the language and what are the ‘observable results’ of executing such programs. For PCF it is reasonable to take the programs to be closed terms of type *nat* or *bool* and to observe the values that result from evaluating such terms. This leads to the definition given on Slide 47.

Contextual equivalence of PCF terms

Given PCF terms M_1, M_2 , PCF type τ , and a type environment Γ , the relation $\Gamma \vdash M_1 \cong_{\text{ctx}} M_2 : \tau$ is defined to hold iff

- Both the typings $\Gamma \vdash M_1 : \tau$ and $\Gamma \vdash M_2 : \tau$ hold.
- For all PCF contexts \mathcal{C} for which $\mathcal{C}[M_1]$ and $\mathcal{C}[M_2]$ are closed terms of type γ , *where* $\gamma = \text{nat}$ or $\gamma = \text{bool}$, and for all values $V : \gamma$,

$$\mathcal{C}[M_1] \Downarrow_{\gamma} V \Leftrightarrow \mathcal{C}[M_2] \Downarrow_{\gamma} V.$$

Slide 47

Definition 5.5.1 (Contexts). The notation $\mathcal{C}[M]$ used on Slide 47 indicates a PCF term containing occurrences of a term M , and then $\mathcal{C}[M']$ is the term that results from replacing these occurrences by M' . More precisely, the *PCF contexts* are generated by the grammar for PCF expressions augmented by the symbol ‘ $-$ ’ representing a place, or ‘hole’ that can be filled with a PCF term:

$$\begin{aligned} \mathcal{C} ::= & - \mid \mathbf{0} \mid \mathbf{succ}(\mathcal{C}) \mid \mathbf{pred}(\mathcal{C}) \mid \mathbf{zero}(\mathcal{C}) \mid \mathbf{true} \mid \mathbf{false} \\ & \mid \mathbf{if} \ \mathcal{C} \ \mathbf{then} \ \mathcal{C} \ \mathbf{else} \ \mathcal{C} \mid x \mid \mathbf{fn} \ x : \tau . \mathcal{C} \mid \mathcal{C} \ \mathcal{C} \mid \mathbf{fix}(\mathcal{C}) \end{aligned}$$

Given such a context \mathcal{C} ,¹ we write $\mathcal{C}[M]$ for the PCF expression that results from replacing all the occurrences of $-$ in \mathcal{C} by M . This form of substitution may well involve the capture of free variables in M by binders in \mathcal{C} . For example, if \mathcal{C} is $\mathbf{fn} \ x : \tau . -$, then $\mathcal{C}[x]$ is $\mathbf{fn} \ x : \tau . x$. Nevertheless it is possible to show that if M and M' are α -convertible then so are $\mathcal{C}[M]$ and $\mathcal{C}[M']$. Hence the operation on PCF expressions sending M to $\mathcal{C}[M]$ induces a well-defined operation on PCF *terms* (= α -equivalence classes of expressions).

¹It is common practice to write $\mathcal{C}[-]$ instead of \mathcal{C} to indicate the symbol being used to mark the ‘holes’ in \mathcal{C} .

Notation 5.5.2. For closed PCF terms, we write

$$M_1 \cong_{\text{ctx}} M_2 : \tau$$

for $\emptyset \vdash M_1 \cong_{\text{ctx}} M_2 : \tau$.

Although \cong_{ctx} is a natural notion of semantic equivalence for PCF given its operational semantics, it is hard to work with, because of the universal quantification over contexts that occurs in the definition.

5.6 Denotational semantics

We aim to give a denotational semantics to PCF that is compositional (cf. Slide 2) and that matches its operational semantics. These requirements are made more precise on Slide 48.

PCF denotational semantics — aims

- PCF types $\tau \mapsto$ domains $\llbracket \tau \rrbracket$.
- Closed PCF terms $M : \tau \mapsto$ elements $\llbracket M \rrbracket \in \llbracket \tau \rrbracket$.
Denotations of open terms will be continuous functions.
- *Compositionality*.
In particular: $\llbracket M \rrbracket = \llbracket M' \rrbracket \Rightarrow \llbracket \mathcal{C}[M] \rrbracket = \llbracket \mathcal{C}[M'] \rrbracket$.
- *Soundness*.
For any type τ , $M \Downarrow_{\tau} V \Rightarrow \llbracket M \rrbracket = \llbracket V \rrbracket$.
- *Adequacy*.
For $\tau = \text{bool}$ or nat , $\llbracket M \rrbracket = \llbracket V \rrbracket \in \llbracket \tau \rrbracket \implies M \Downarrow_{\tau} V$.

Slide 48

The *soundness* and *adequacy* properties make precise the connection between the operational and denotational semantics for which we are aiming. Note that the adequacy property only involves the ‘ground’ datatypes *nat* and *bool*. One cannot expect such a property to hold at function types because of the ‘intensional’ nature of values at such types (mentioned above). Indeed such an adequacy property at function types would contradict the compositionality and soundness properties we want for $\llbracket - \rrbracket$, as the following example shows.

Example 5.6.1. Consider the following two PCF value terms of type $\text{nat} \rightarrow \text{nat}$:

$$V \stackrel{\text{def}}{=} \mathbf{fn} x : \text{nat} . (\mathbf{fn} y : \text{nat} . y) \mathbf{0} \quad \text{and} \quad V' \stackrel{\text{def}}{=} \mathbf{fn} x : \text{nat} . \mathbf{0}.$$

Now $V \not\Downarrow_{\text{nat} \rightarrow \text{nat}} V'$, since by $(\Downarrow_{\text{val}})$, $V \Downarrow_{\text{nat} \rightarrow \text{nat}} V \neq V'$ and by Proposition 5.4.1 evaluation is deterministic. However, the soundness and compositionality properties of $\llbracket - \rrbracket$ imply that $\llbracket V \rrbracket = \llbracket V' \rrbracket$. For using $(\Downarrow_{\text{val}})$ and $(\Downarrow_{\text{cbn}})$ we have

$$(\mathbf{fn} y : \text{nat} . y) \mathbf{0} \Downarrow_{\text{nat}} \mathbf{0}.$$

So by soundness $\llbracket (\mathbf{fn} y : \text{nat} . y) \mathbf{0} \rrbracket = \llbracket \mathbf{0} \rrbracket$. Therefore by compositionality for $\mathcal{C}[-] \stackrel{\text{def}}{=} \mathbf{fn} x : \text{nat} . -$ we have

$$\llbracket \mathcal{C}[(\mathbf{fn} y : \text{nat} . y) \mathbf{0}] \rrbracket = \llbracket \mathcal{C}[\mathbf{0}] \rrbracket$$

i.e. $\llbracket V \rrbracket = \llbracket V' \rrbracket$. □

As the theorem stated on Slide 49 shows, if we have a denotational semantics of PCF satisfying the properties on Slide 48, we can use it to establish instances of contextual equivalence by showing that terms have equal denotation. In many cases this is an easier task than proving contextual equivalence directly from the definition. The theorem on Slide 49 generalises to open terms: if the continuous functions that are the denotations of two open terms (of the same type for some type environment) are equal, then the terms are contextually equivalent.

Theorem. For all types τ and closed terms $M_1, M_2 \in \text{PCF}_\tau$, if $\llbracket M_1 \rrbracket$ and $\llbracket M_2 \rrbracket$ are equal elements of the domain $\llbracket \tau \rrbracket$, then $M_1 \cong_{\text{ctx}} M_2 : \tau$.

Proof.

$$\mathcal{C}[M_1] \Downarrow_{\text{nat}} V \Rightarrow \llbracket \mathcal{C}[M_1] \rrbracket = \llbracket V \rrbracket \quad (\text{soundness})$$

$$\Rightarrow \llbracket \mathcal{C}[M_2] \rrbracket = \llbracket V \rrbracket \quad (\text{compositionality on } \llbracket M_1 \rrbracket = \llbracket M_2 \rrbracket)$$

$$\Rightarrow \mathcal{C}[M_2] \Downarrow_{\text{nat}} V \quad (\text{adequacy})$$

and symmetrically. □

Proof principle

To prove

$$M_1 \cong_{\text{ctx}} M_2 : \tau$$

it suffices to establish

$$\llbracket M_1 \rrbracket = \llbracket M_2 \rrbracket \text{ in } \llbracket \tau \rrbracket$$

? The proof principle is sound, but is it complete? That is, is equality in the denotational model also a necessary condition for contextual equivalence?

Slide 50

5.7 Exercises

Exercise 5.7.1. Carry out the suggested proof of Proposition 5.4.1.

Exercise 5.7.2. Recall that Church's fixpoint combinator in the untyped lambda calculus is $Y \stackrel{\text{def}}{=} \lambda f. (\lambda x. f(x x)) (\lambda x. f(x x))$. Show that there are no PCF types τ_1, τ_2, τ_3 so that the typing relation

$$\emptyset \vdash \mathbf{fn} f : \tau_1. (\mathbf{fn} x : \tau_2. f(x x)) (\mathbf{fn} x : \tau_2. f(x x)) : \tau_3$$

is provable from the axioms and rules in Figure 2.

Exercise 5.7.3. Define the following PCF terms:

$$\begin{aligned} plus &\stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} p : nat \rightarrow (nat \rightarrow nat) . \mathbf{fn} x : nat . \mathbf{fn} y : nat . \\ &\quad \mathbf{if} \mathbf{zero}(y) \mathbf{then} x \mathbf{else} \mathbf{succ}(p x \mathbf{pred}(y))) \end{aligned}$$

$$\begin{aligned} times &\stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} t : nat \rightarrow (nat \rightarrow nat) . \mathbf{fn} x : nat . \mathbf{fn} y : nat . \\ &\quad \mathbf{if} \mathbf{zero}(y) \mathbf{then} \mathbf{0} \mathbf{else} plus (t x \mathbf{pred}(y)) x) \end{aligned}$$

$$\begin{aligned} fact &\stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} f : nat \rightarrow nat . \mathbf{fn} x : nat . \\ &\quad \mathbf{if} \mathbf{zero}(x) \mathbf{then} \mathbf{succ}(\mathbf{0}) \mathbf{else} times x(f \mathbf{pred}(x))). \end{aligned}$$

Show by induction on $n \in \mathbb{N}$ that for all $m \in \mathbb{N}$

$$\begin{aligned} plus \mathbf{succ}^m(\mathbf{0}) \mathbf{succ}^n(\mathbf{0}) &\Downarrow_{nat} \mathbf{succ}^{m+n}(\mathbf{0}) \\ times \mathbf{succ}^m(\mathbf{0}) \mathbf{succ}^n(\mathbf{0}) &\Downarrow_{nat} \mathbf{succ}^{m*n}(\mathbf{0}) \\ fact \mathbf{succ}^n(\mathbf{0}) &\Downarrow_{nat} \mathbf{succ}!n(\mathbf{0}). \end{aligned}$$

6 Denotational Semantics of PCF

We turn now to the task of showing that PCF has a denotational semantics with the properties of compositionality, soundness, and adequacy.

Denotational semantics of PCF

To every typing judgement

$$\Gamma \vdash M : \tau$$

we associate a continuous function

$$\llbracket \Gamma \vdash M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$$

between domains.

Slide 51

6.1 Denotation of types

For each PCF type τ , we define a domain $\llbracket \tau \rrbracket$ by induction on the structure of τ as on Slide 52.

Denotational semantics of PCF types

$\llbracket nat \rrbracket \stackrel{\text{def}}{=} \mathbb{N}_\perp$	(flat domain)
$\llbracket bool \rrbracket \stackrel{\text{def}}{=} \mathbb{B}_\perp$	(flat domain)
$\llbracket \tau \rightarrow \tau' \rrbracket \stackrel{\text{def}}{=} \llbracket \tau \rrbracket \rightarrow \llbracket \tau' \rrbracket$	(function domain).

where $\mathbb{N} = \{0, 1, 2, \dots\}$ and $\mathbb{B} = \{true, false\}$.

Slide 52

6.2 Denotation of terms

For each PCF term M and type environment Γ , recall from Proposition 5.3.1 that there is at most one type τ for which the typing relation $\Gamma \vdash M : \tau$ is derivable from the axioms and rules in Figure 2. We only give a denotational semantics to such typeable terms. Specifically, given such M and Γ , we will define a continuous function between domains

$$(8) \quad \llbracket \Gamma \vdash M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$$

where τ is the type for which $\Gamma \vdash M : \tau$ holds, and where $\llbracket \Gamma \rrbracket$ is the following dependent product domain (see Definition 3.2.3):

$$(9) \quad \llbracket \Gamma \rrbracket \stackrel{\text{def}}{=} \prod_{x \in \text{dom}(\Gamma)} \llbracket \Gamma(x) \rrbracket.$$

The elements of the domain (9) will be called Γ -*environments*: they are functions ρ mapping each variable x in the domain of definition of Γ to an element $\rho(x) \in \llbracket \Gamma(x) \rrbracket$ in the domain which is the denotation of the type $\Gamma(x)$ assigned to x by the type environment Γ .

Denotational semantics of PCF type environments

$$\begin{aligned} \llbracket \Gamma \rrbracket &\stackrel{\text{def}}{=} \prod_{x \in \text{dom}(\Gamma)} \llbracket \Gamma(x) \rrbracket \quad (\Gamma\text{-environments}) \\ &= \text{the domain of partial functions } \rho \text{ from variables} \\ &\quad \text{to domains such that } \text{dom}(\rho) = \text{dom}(\Gamma) \text{ and} \\ &\quad \rho(x) \in \llbracket \Gamma(x) \rrbracket \text{ for all } x \in \text{dom}(\Gamma) \end{aligned}$$

Example:

1. For the empty type environment \emptyset ,

$$\llbracket \emptyset \rrbracket = \{ \perp \}$$

where \perp denotes the unique partial function with $\text{dom}(\perp) = \emptyset$.

Slide 53

2. $\llbracket \langle x \mapsto \tau \rangle \rrbracket = (\{x\} \rightarrow \llbracket \tau \rrbracket) \cong \llbracket \tau \rrbracket$

- 3.

$$\begin{aligned} &\llbracket \langle x_1 \mapsto \tau_1, \dots, x_n \mapsto \tau_n \rangle \rrbracket \\ &\cong (\{x_1\} \rightarrow \llbracket \tau_1 \rrbracket) \times \dots \times (\{x_n\} \rightarrow \llbracket \tau_n \rrbracket) \\ &\cong \llbracket \tau_1 \rrbracket \times \dots \times \llbracket \tau_n \rrbracket \end{aligned}$$

Slide 54

The continuous function (8) is defined by induction on the structure of M , or equivalently, by induction on the derivation of the typing relation $\Gamma \vdash M : \tau$. The definition is given on Slides 55–59, where we show the effect of each function on a Γ -environment, ρ .

Denotational semantics of PCF terms, I

$$\llbracket \Gamma \vdash \mathbf{0} \rrbracket(\rho) \stackrel{\text{def}}{=} 0 \in \llbracket \text{nat} \rrbracket$$

$$\llbracket \Gamma \vdash \mathbf{true} \rrbracket(\rho) \stackrel{\text{def}}{=} \text{true} \in \llbracket \text{bool} \rrbracket$$

$$\llbracket \Gamma \vdash \mathbf{false} \rrbracket(\rho) \stackrel{\text{def}}{=} \text{false} \in \llbracket \text{bool} \rrbracket$$

$$\llbracket \Gamma \vdash x \rrbracket(\rho) \stackrel{\text{def}}{=} \rho(x) \in \llbracket \Gamma(x) \rrbracket \quad (x \in \text{dom}(\Gamma))$$

Slide 55

Denotational semantics of PCF terms, II

$$\begin{aligned} & \llbracket \Gamma \vdash \mathbf{succ}(M) \rrbracket(\rho) \\ & \stackrel{\text{def}}{=} \begin{cases} \llbracket \Gamma \vdash M \rrbracket(\rho) + 1 & \text{if } \llbracket \Gamma \vdash M \rrbracket(\rho) \neq \perp \\ \perp & \text{if } \llbracket \Gamma \vdash M \rrbracket(\rho) = \perp \end{cases} \\ & \llbracket \Gamma \vdash \mathbf{pred}(M) \rrbracket(\rho) \\ & \stackrel{\text{def}}{=} \begin{cases} \llbracket \Gamma \vdash M \rrbracket(\rho) - 1 & \text{if } \llbracket \Gamma \vdash M \rrbracket(\rho) > 0 \\ \perp & \text{if } \llbracket \Gamma \vdash M \rrbracket(\rho) = 0, \perp \end{cases} \\ & \llbracket \Gamma \vdash \mathbf{zero}(M) \rrbracket(\rho) \stackrel{\text{def}}{=} \begin{cases} \mathit{true} & \text{if } \llbracket \Gamma \vdash M \rrbracket(\rho) = 0 \\ \mathit{false} & \text{if } \llbracket \Gamma \vdash M \rrbracket(\rho) > 0 \\ \perp & \text{if } \llbracket \Gamma \vdash M \rrbracket(\rho) = \perp \end{cases} \end{aligned}$$

Slide 56

Denotational semantics of PCF terms, III

$$\begin{aligned} & \llbracket \Gamma \vdash \mathbf{if } M_1 \mathbf{ then } M_2 \mathbf{ else } M_3 \rrbracket(\rho) \\ & \stackrel{\text{def}}{=} \begin{cases} \llbracket \Gamma \vdash M_2 \rrbracket(\rho) & \text{if } \llbracket \Gamma \vdash M_1 \rrbracket(\rho) = \mathit{true} \\ \llbracket \Gamma \vdash M_3 \rrbracket(\rho) & \text{if } \llbracket \Gamma \vdash M_1 \rrbracket(\rho) = \mathit{false} \\ \perp & \text{if } \llbracket \Gamma \vdash M_1 \rrbracket(\rho) = \perp \end{cases} \\ & \llbracket \Gamma \vdash M_1 M_2 \rrbracket(\rho) \stackrel{\text{def}}{=} (\llbracket \Gamma \vdash M_1 \rrbracket(\rho)) (\llbracket \Gamma \vdash M_2 \rrbracket(\rho)) \end{aligned}$$

Slide 57

Denotational semantics of PCF terms, IV

$$\begin{aligned} & \llbracket \Gamma \vdash \mathbf{fn} \ x : \tau . M \rrbracket (\rho) \\ & \stackrel{\text{def}}{=} \lambda d \in \llbracket \tau \rrbracket . \llbracket \Gamma[x \mapsto \tau] \vdash M \rrbracket (\rho[x \mapsto d]) \quad (x \notin \text{dom}(\Gamma)) \end{aligned}$$

NB: $\rho[x \mapsto d] \in \llbracket \Gamma[x \mapsto \tau] \rrbracket$ is the function mapping x to $d \in \llbracket \tau \rrbracket$ and otherwise acting like ρ .

Slide 58

Denotational semantics of PCF terms, V

$$\llbracket \Gamma \vdash \mathbf{fix}(M) \rrbracket (\rho) \stackrel{\text{def}}{=} \text{fix}(\llbracket \Gamma \vdash M \rrbracket (\rho))$$

Recall that fix is the function assigning least fixed points to continuous functions.

Slide 59

Denotational semantics of PCF

Proposition. *For all typing judgements $\Gamma \vdash M : \tau$, the denotation*

$$\llbracket \Gamma \vdash M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$$

is a well-defined continuous function.

Slide 60

$\llbracket \Gamma \vdash M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$ is a well-defined continuous function because the base cases of the definition (on Slide 55) are continuous functions and at each induction step, in giving the denotation of a compound phrase in terms of the denotations of its immediate subphrases, we make use of constructions preserving continuity—as we now indicate.

0, true, and false: The denotation of these terms (Slide 55) are all functions that are constantly equal to a particular value. We noted in Example 2.3.8 that such functions are continuous.

variables: The denotation of a variable (Slide 55) is a projection function. We noted in Definition 3.2.3 that such functions are continuous, because of the way lubs are computed componentwise in dependent product domains.

succ, pred, and zero: We need to make use of the fact that composition of functions preserves continuity—see the Proposition on Slide 37. We leave its proof as a simple exercise. In particular, the denotation of $\text{succ}(M)$ (Slide 56) is the composition

$$s_{\perp} \circ \llbracket \Gamma \vdash M \rrbracket$$

where by induction hypothesis $\llbracket \Gamma \vdash M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \mathbb{N}_{\perp}$ is a continuous function, and where $s_{\perp} : \mathbb{N}_{\perp} \rightarrow \mathbb{N}_{\perp}$ is the continuous function on the flat domain \mathbb{N}_{\perp} induced, as

in Proposition 3.1.1, by the function $s : \mathbb{N} \rightarrow \mathbb{N}$ mapping each n to $n + 1$.

Similarly

$$\llbracket \Gamma \vdash \mathbf{pred}(M) \rrbracket = p_{\perp} \circ \llbracket \Gamma \vdash M \rrbracket \text{ and } \llbracket \Gamma \vdash \mathbf{zero}(M) \rrbracket = z_{\perp} \circ \llbracket \Gamma \vdash M \rrbracket,$$

for suitable functions $p : \mathbb{N} \rightarrow \mathbb{N}$ and $z : \mathbb{N} \rightarrow \mathbb{B}$. (Only p is a properly partial function, undefined at 0; s and z are totally defined functions.)

conditional: By induction hypothesis we have continuous functions $\llbracket \Gamma \vdash M_1 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \mathbb{B}_{\perp}$, $\llbracket \Gamma \vdash M_2 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$, and $\llbracket \Gamma \vdash M_3 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$. Then $\llbracket \Gamma \vdash \mathbf{if} M_1 \mathbf{then} M_2 \mathbf{else} M_3 \rrbracket$ is continuous because we can express the definition on Slide 57 in terms of composition, the pairing operation of Proposition 3.2.1, and the continuous function $\cdot : \mathbb{B}_{\perp} \times (\llbracket \tau \rrbracket \times \llbracket \tau \rrbracket) \rightarrow \llbracket \tau \rrbracket$ of Proposition 3.2.2:

$$\llbracket \Gamma \vdash \mathbf{if} M_1 \mathbf{then} M_2 \mathbf{else} M_3 \rrbracket = \mathit{if} \circ \langle \llbracket \Gamma \vdash M_1 \rrbracket, \langle \llbracket \Gamma \vdash M_2 \rrbracket, \llbracket \Gamma \vdash M_3 \rrbracket \rangle \rangle.$$

application: By induction hypothesis we have continuous functions $\llbracket \Gamma \vdash M_1 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow (\llbracket \tau \rrbracket \rightarrow \llbracket \tau' \rrbracket)$ and $\llbracket \Gamma \vdash M_2 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$. Then $\llbracket \Gamma \vdash M_1 M_2 \rrbracket$ is continuous because we can express the definition on Slide 57 in terms of composition, pairing, and the evaluation function $ev : (\llbracket \tau \rrbracket \rightarrow \llbracket \tau' \rrbracket) \times \llbracket \tau \rrbracket \rightarrow \llbracket \tau' \rrbracket$ that we proved continuous in Proposition 3.3.1:

$$\llbracket \Gamma \vdash M_1 M_2 \rrbracket = ev \circ \langle \llbracket \Gamma \vdash M_1 \rrbracket, \llbracket \Gamma \vdash M_2 \rrbracket \rangle.$$

function abstraction: By induction hypothesis we have a continuous function $\llbracket \Gamma[x \mapsto \tau] \vdash M \rrbracket : \llbracket \Gamma[x \mapsto \tau] \rrbracket \rightarrow \llbracket \tau' \rrbracket$ with $x \notin \mathit{dom}(\Gamma)$. Note that each $\Gamma[x \mapsto \tau]$ -environment, $\rho' \in \llbracket \Gamma[x \mapsto \tau] \rrbracket$, can be uniquely expressed as $\rho[x \mapsto d]$, where ρ is the restriction of the function ρ' to $\mathit{dom}(\Gamma)$ and where $d = \rho'(x)$; furthermore the partial order respects this decomposition: $\rho_1[x \mapsto d_1] \sqsubseteq \rho_2[x \mapsto d_2]$ in $\llbracket \Gamma[x \mapsto \tau] \rrbracket$ iff $\rho_1 \sqsubseteq \rho_2$ in $\llbracket \Gamma \rrbracket$ and $d_1 \sqsubseteq d_2$ in $\llbracket \tau \rrbracket$. Thus we can identify $\llbracket \Gamma[x \mapsto \tau] \rrbracket$ with the binary product domain $\llbracket \Gamma \rrbracket \times \llbracket \tau \rrbracket$. So we can apply the ‘Currying’ operation of Proposition 3.3.1 to obtain a continuous function

$$\mathit{cur}(\llbracket \Gamma[x \mapsto \tau] \vdash M \rrbracket) : \llbracket \Gamma \rrbracket \rightarrow (\llbracket \tau \rrbracket \rightarrow \llbracket \tau' \rrbracket) = \llbracket \tau \rightarrow \tau' \rrbracket.$$

But this is precisely the function used to define $\llbracket \Gamma \vdash \mathbf{fn} x : \tau . M \rrbracket$ on Slide 58.

fixpoints: By induction hypothesis we have a continuous function $\llbracket \Gamma \vdash M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rightarrow \tau \rrbracket$. Now $\llbracket \tau \rightarrow \tau \rrbracket$ is the function domain $\llbracket \tau \rrbracket \rightarrow \llbracket \tau \rrbracket$ and from the definition on Slide 58 we have that $\llbracket \Gamma \vdash \mathbf{fix}(M) \rrbracket = \mathit{fix} \circ \llbracket \Gamma \vdash M \rrbracket$ is the composition with the function $\mathit{fix} : (\llbracket \tau \rrbracket \rightarrow \llbracket \tau \rrbracket) \rightarrow \llbracket \tau \rrbracket$ assigning least fixpoints, which we proved continuous in the Proposition on Slide 38.

Denotations of closed terms

If $M \in \text{PCF}_\tau$, then by definition $\emptyset \vdash M : \tau$ holds, so we get $\llbracket \emptyset \vdash M \rrbracket : \llbracket \emptyset \rrbracket \rightarrow \llbracket \tau \rrbracket$.

When $\Gamma = \emptyset$, the only Γ -environment is the totally undefined partial function—call it \perp .

So in this case $\llbracket \Gamma \rrbracket$ is a one-element domain, $\{\perp\}$. Continuous functions $f : \{\perp\} \rightarrow D$ are in bijection with elements $f(\perp) \in D$, and in particular we can identify the denotation of closed PCF terms with elements of the domain denoting their type:

$$\llbracket M \rrbracket \stackrel{\text{def}}{=} \llbracket \emptyset \vdash M \rrbracket(\perp) \in \llbracket \tau \rrbracket \quad (M \in \text{PCF}_\tau)$$

Slide 61

6.3 Compositionality

The fact that the denotational semantics of PCF terms is *compositional*—i.e. that the denotation of a compound term is a function of the denotations of its immediate subterms—is part and parcel of the definition of $\llbracket \Gamma \vdash M \rrbracket$ by induction on the structure of M . So in particular, each of the ways of constructing terms in PCF respects equality of denotations: this is summarised in Figure 5. Then the property of closed terms stated on Slide 48, *viz.*

$$\llbracket M \rrbracket = \llbracket M' \rrbracket \Rightarrow \llbracket \mathcal{C}[M] \rrbracket = \llbracket \mathcal{C}[M'] \rrbracket$$

follows from this by induction on the structure of the context $\mathcal{C}[-]$. More generally, for open terms we have

Proposition 6.3.1. *Suppose*

$$\llbracket \Gamma \vdash M \rrbracket = \llbracket \Gamma \vdash M' \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$$

and that $\mathcal{C}[-]$ is a PCF context such that $\Gamma' \vdash \mathcal{C}[M] : \tau'$ and $\Gamma' \vdash \mathcal{C}[M'] : \tau'$ hold for some type τ' and some type environment Γ' . Then

$$\llbracket \Gamma' \vdash \mathcal{C}[M] \rrbracket = \llbracket \Gamma' \vdash \mathcal{C}[M'] \rrbracket : \llbracket \Gamma' \rrbracket \rightarrow \llbracket \tau' \rrbracket.$$

-
- If $\llbracket \Gamma \vdash M \rrbracket = \llbracket \Gamma \vdash M' \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket nat \rrbracket$, then

$$\llbracket \Gamma \vdash \mathbf{op}(M) \rrbracket = \llbracket \Gamma \vdash \mathbf{op}(M') \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$$

(where $\mathbf{op} = \mathbf{succ}$, \mathbf{pred} and $\tau = nat$, or $\mathbf{op} = \mathbf{zero}$ and $\tau = bool$).

- If $\llbracket \Gamma \vdash M_1 \rrbracket = \llbracket \Gamma \vdash M'_1 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket bool \rrbracket$, $\llbracket \Gamma \vdash M_2 \rrbracket = \llbracket \Gamma \vdash M'_2 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$, and $\llbracket \Gamma \vdash M_3 \rrbracket = \llbracket \Gamma \vdash M'_3 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$, then

$$\llbracket \Gamma \vdash \mathbf{if} M_1 \mathbf{then} M_2 \mathbf{else} M_3 \rrbracket = \llbracket \Gamma \vdash \mathbf{if} M'_1 \mathbf{then} M'_2 \mathbf{else} M'_3 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket.$$

- If $\llbracket \Gamma \vdash M_1 \rrbracket = \llbracket \Gamma \vdash M'_1 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rightarrow \tau' \rrbracket$ and $\llbracket \Gamma \vdash M_2 \rrbracket = \llbracket \Gamma \vdash M'_2 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket$, then

$$\llbracket \Gamma \vdash M_1 M_2 \rrbracket = \llbracket \Gamma \vdash M'_1 M'_2 \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau' \rrbracket.$$

- If $\llbracket \Gamma[x \mapsto \tau] \vdash M \rrbracket = \llbracket \Gamma[x \mapsto \tau] \vdash M' \rrbracket : \llbracket \Gamma[x \mapsto \tau] \rrbracket \rightarrow \llbracket \tau' \rrbracket$, then

$$\llbracket \Gamma \vdash \mathbf{fn} x : \tau . M \rrbracket = \llbracket \Gamma \vdash \mathbf{fn} x : \tau . M' \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rightarrow \tau' \rrbracket.$$

- If $\llbracket \Gamma \vdash M \rrbracket = \llbracket \Gamma \vdash M' \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rightarrow \tau \rrbracket$, then

$$\llbracket \Gamma \vdash \mathbf{fix}(M) \rrbracket = \llbracket \Gamma \vdash \mathbf{fix}(M') \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \tau \rrbracket.$$

Figure 5: Compositionality properties of $\llbracket - \rrbracket$

Substitution property of $\llbracket - \rrbracket$

Proposition. *Suppose*

$$\Gamma \vdash M : \tau$$

$$\Gamma[x \mapsto \tau] \vdash M' : \tau'$$

(so that by Proposition 5.3.1(ii) we also have $\Gamma \vdash M'[M/x] : \tau'$). Then for all $\rho \in \llbracket \Gamma \rrbracket$

$$\llbracket \Gamma \vdash M'[M/x] \rrbracket(\rho) = \llbracket \Gamma[x \mapsto \tau] \vdash M' \rrbracket(\rho[x \mapsto \llbracket \Gamma \vdash M \rrbracket]).$$

In particular when $\Gamma = \emptyset$, $\llbracket x \mapsto \tau \vdash M' \rrbracket : \llbracket \tau \rrbracket \rightarrow \llbracket \tau' \rrbracket$ and

$$\llbracket M'[M/x] \rrbracket = \llbracket x \mapsto \tau \vdash M' \rrbracket(\llbracket M \rrbracket)$$

Slide 62

The substitution property stated on Slide 62 gives another aspect of the compositional nature of the denotational semantics of PCF. It can be proved by induction on the structure of the term M' .

6.4 Soundness

The second of the aims mentioned on Slide 48 is to show that if a closed PCF term M evaluates to a value V in the operational semantics, then M and V have the same denotation.

Theorem 6.4.1. *For all PCF types τ and all closed terms $M, V \in \text{PCF}_\tau$ with V a value, if $M \Downarrow_\tau V$ is derivable from the axioms and rules in Figure 3 then $\llbracket M \rrbracket$ and $\llbracket V \rrbracket$ are equal elements of the domain $\llbracket \tau \rrbracket$.*

Proof. One uses Rule Induction for the inductively defined relation \Downarrow . Specifically, defining

$$\Phi(M, \tau, V) \stackrel{\text{def}}{\iff} \llbracket M \rrbracket = \llbracket V \rrbracket \in \llbracket \tau \rrbracket$$

one shows that the property $\Phi(M, \tau, V)$ is closed under the axioms and rules in Figure 3. We give the argument for rules $(\Downarrow_{\text{cbn}})$ and $(\Downarrow_{\text{fix}})$, and leave the others as easy exercises.

Case (\Downarrow_{cbn}). Suppose

$$(10) \quad \llbracket M_1 \rrbracket = \llbracket \mathbf{fn} \ x : \tau . M'_1 \rrbracket \in \llbracket \tau \rightarrow \tau' \rrbracket$$

$$(11) \quad \llbracket M'_1[M_2/x] \rrbracket = \llbracket V \rrbracket \in \llbracket \tau' \rrbracket.$$

We have to prove that $\llbracket M_1 M_2 \rrbracket = \llbracket V \rrbracket \in \llbracket \tau' \rrbracket$. But

$$\begin{aligned} \llbracket M_1 M_2 \rrbracket &= \llbracket M_1 \rrbracket(\llbracket M_2 \rrbracket) && \text{by Slide 57} \\ &= \llbracket \mathbf{fn} \ x : \tau . M'_1 \rrbracket(\llbracket M_2 \rrbracket) && \text{by (10)} \\ &= (\lambda d \in \llbracket \tau \rrbracket . \llbracket x \mapsto \tau \vdash M'_1 \rrbracket(d))(\llbracket M_2 \rrbracket) && \text{by Slide 58} \\ &= \llbracket x \mapsto \tau \vdash M'_1 \rrbracket(\llbracket M_2 \rrbracket) \\ &= \llbracket M'_1[M_2/x] \rrbracket && \text{by Slide 62} \\ &= \llbracket V \rrbracket && \text{by (11).} \end{aligned}$$

Case (\Downarrow_{fix}). Suppose

$$(12) \quad \llbracket M \mathbf{fix}(M) \rrbracket = \llbracket V \rrbracket \in \llbracket \tau \rrbracket.$$

We have to prove that $\llbracket \mathbf{fix}(M) \rrbracket = \llbracket V \rrbracket \in \llbracket \tau \rrbracket$. But

$$\begin{aligned} \llbracket \mathbf{fix}(M) \rrbracket &= \mathit{fix}(\llbracket M \rrbracket) && \text{by Slide 58} \\ &= \llbracket M \rrbracket(\mathit{fix}(\llbracket M \rrbracket)) && \text{by fixed point property of } \mathit{fix} \\ &= \llbracket M \rrbracket \llbracket \mathbf{fix}(M) \rrbracket && \text{by Slide 58} \\ &= \llbracket M \mathbf{fix}(M) \rrbracket && \text{by Slide 57} \\ &= \llbracket V \rrbracket && \text{by (12).} \end{aligned}$$

□

We have now established two of the three properties of the denotational semantics of PCF stated on Slide 48 (and which in particular are needed to use denotational equality to prove PCF contextual equivalences). The third property, *adequacy*, is not so easy to prove as are the first two. We postpone the proof until we have introduced a useful principle of induction tailored to reasoning about least fixed points. This is the subject of the next section.

6.5 Exercises

Exercise 6.5.1. Prove the Proposition on Slide 62.

Exercise 6.5.2. Defining $\Omega_\tau \stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} \ x : \tau . x)$, show that $\llbracket \Omega_\tau \rrbracket$ is the least element \perp of the domain $\llbracket \tau \rrbracket$. Deduce that $\llbracket \mathbf{fn} \ x : \tau . \Omega_\tau \rrbracket = \llbracket \Omega_{\tau \rightarrow \tau} \rrbracket$.

7 Relating Denotational and Operational Semantics

We have already seen (in Section 6.4) that the denotational semantics of PCF given in Section 6 is *sound* for the operational semantics, in the sense defined on Slide 48. Here we prove the property of *adequacy* defined on that slide. So we have to prove for any closed PCF terms M and V of type $\tau = \text{nat}$ or bool with V a value, that

$$\llbracket M \rrbracket = \llbracket V \rrbracket \Rightarrow M \Downarrow_{\tau} V.$$

Perhaps surprisingly, this is not easy to prove. We will employ a method due to Plotkin (although not quite the one used in his original paper on PCF, Plotkin 1977) and Mulmuley (1987) making use of the following notion of ‘formal approximation’ relations.

Adequacy

For any closed PCF terms M and V of *ground* type
 $\gamma \in \{\text{nat}, \text{bool}\}$ with V a value

$$\llbracket M \rrbracket = \llbracket V \rrbracket \in \llbracket \gamma \rrbracket \implies M \Downarrow_{\gamma} V.$$

NB. Adequacy does not hold at function types:

$$\llbracket \text{fn } x : \tau. (\text{fn } y : \tau. y) x \rrbracket = \llbracket \text{fn } x : \tau. x \rrbracket : \llbracket \tau \rrbracket \rightarrow \llbracket \tau \rrbracket$$

but

$$\text{fn } x : \tau. (\text{fn } y : \tau. y) x \not\Downarrow_{\tau \rightarrow \tau} \text{fn } x : \tau. x$$

Slide 63

7.1 Formal approximation relations

We define a certain family of binary relations

$$\triangleleft_{\tau} \subseteq \llbracket \tau \rrbracket \times \text{PCF}_{\tau}$$

indexed by the PCF types, τ . Thus each \triangleleft_{τ} relates elements of the domain $\llbracket \tau \rrbracket$ to closed PCF terms of type τ . We use infix notation and write $d \triangleleft_{\tau} M$ instead of $(d, M) \in \triangleleft_{\tau}$. The definition of these relations \triangleleft_{τ} proceeds *by induction on the*

structure of the type τ and is given on Slide 64. (Read the definition in conjunction with the definition of $\llbracket \tau \rrbracket$ given on Slide 52.)

The key property of the relations \triangleleft_τ is that they are respected by the various syntax-forming operations of the PCF language. This is summed up by the Proposition on Slide 65 which makes use of the following terminology.

Definition 7.1.1. For each typing environment Γ (= a finite partial function from variables to PCF types), a Γ -substitution σ is a function mapping each variable $x \in \text{dom}(\Gamma)$ to a closed PCF term $\sigma(x)$ of type $\Gamma(x)$. Recall from Section 6.2 that a Γ -environment ρ is a function mapping each variable $x \in \text{dom}(\Gamma)$ to an element $\rho(x)$ of the domain $\llbracket \Gamma(x) \rrbracket$. We define

$$\rho \triangleleft_\Gamma \sigma \stackrel{\text{def}}{\Leftrightarrow} \forall x \in \text{dom}(\Gamma). \rho(x) \triangleleft_{\Gamma(x)} \sigma(x).$$

Definition of $d \triangleleft_\tau M$ ($d \in \llbracket \tau \rrbracket, M \in \text{PCF}_\tau$)

$$d \triangleleft_{\text{nat}} M \stackrel{\text{def}}{\Leftrightarrow} (d \in \mathbb{N} \Rightarrow M \Downarrow_{\text{nat}} \mathbf{succ}^d(\mathbf{0}))$$

$$d \triangleleft_{\text{bool}} M \stackrel{\text{def}}{\Leftrightarrow} (d = \text{true} \Rightarrow M \Downarrow_{\text{bool}} \mathbf{true}) \\ \& (d = \text{false} \Rightarrow M \Downarrow_{\text{bool}} \mathbf{false})$$

$$d \triangleleft_{\tau \rightarrow \tau'} M \stackrel{\text{def}}{\Leftrightarrow} \forall e, N (e \triangleleft_\tau N \Rightarrow d(e) \triangleleft_{\tau'} M N)$$

Slide 64

Fundamental property of the relations \triangleleft_τ

Proposition. *If $\Gamma \vdash M : \tau$ is a valid PCF typing, then for all Γ -environments ρ and all Γ -substitutions σ*

$$\rho \triangleleft_\Gamma \sigma \Rightarrow \llbracket \Gamma \vdash M \rrbracket(\rho) \triangleleft_\tau M[\sigma]$$

- $\rho \triangleleft_\Gamma \sigma$ means that $\rho(x) \triangleleft_{\Gamma(x)} \sigma(x)$ holds for each $x \in \text{dom}(\Gamma)$.
- $M[\sigma]$ is the PCF term resulting from the simultaneous substitution of $\sigma(x)$ for x in M , each $x \in \text{dom}(\Gamma)$.

Slide 65

Note that the Fundamental Property of \triangleleft_τ given on Slide 65 specialises in case $\Gamma = \emptyset$ to give

$$\llbracket M \rrbracket \triangleleft_\tau M$$

for all types τ and all closed PCF terms $M : \tau$. (Here we are using the notation for denotations of closed terms introduced on Slide 61.) Using this, we can complete the proof of the adequacy property, as shown on Slide 66.

Proof of $\llbracket M \rrbracket = \llbracket V \rrbracket \Rightarrow M \Downarrow_{\tau} V$ ($\tau = nat, bool$)

Case $\tau = nat$.

$V = \mathbf{succ}^n(\mathbf{0})$ for some $n \in \mathbb{N}$ and hence

$$\begin{aligned} \llbracket M \rrbracket &= \llbracket \mathbf{succ}^n(\mathbf{0}) \rrbracket \\ &\Rightarrow n = \llbracket M \rrbracket \triangleleft_{\tau} M && \text{by Fundamental Property (Slide 65)} \\ &\Rightarrow M \Downarrow \mathbf{succ}^n(\mathbf{0}) && \text{by definition of } \triangleleft_{nat} \end{aligned}$$

Case $\tau = bool$ is similar.

Slide 66

7.2 Proof of the Fundamental Property of \triangleleft

To prove the Proposition on Slide 65 we need the following properties of the formal approximation relations.

Lemma 7.2.1.

- (i) $\perp \triangleleft_{\tau} M$ holds for all $M \in \text{PCF}_{\tau}$.
- (ii) For each $M \in \text{PCF}_{\tau}$, $\{d \mid d \triangleleft_{\tau} M\}$ is a chain-closed subset of the domain $\llbracket \tau \rrbracket$. Hence by (i), it is also an admissible subset (cf. Slide 39).
- (iii) If $d_2 \sqsubseteq d_1$, $d_1 \triangleleft_{\tau} M_1$, and $\forall V (M_1 \Downarrow_{\tau} V \Rightarrow M_2 \Downarrow_{\tau} V)$, then $d_2 \triangleleft_{\tau} M_2$.

Proof. Each of these properties follows easily by induction on the structure of τ , using the definitions of \triangleleft_{τ} and of the evaluation relation \Downarrow_{τ} . \square

Proof of the Proposition on Slide 65 [NON-EXAMINABLE]. We use Rule Induction for the inductively defined typing relation $\Gamma \vdash M : \tau$. Define

$$\Phi(\Gamma, M, \tau) \stackrel{\text{def}}{=} \Gamma \vdash M : \tau \ \& \ \forall \rho, \sigma (\rho \triangleleft_{\Gamma} \sigma \Rightarrow \llbracket \Gamma \vdash M \rrbracket(\rho) \triangleleft_{\tau} M[\sigma])$$

Then it suffices to show that Φ is closed under the axioms and rules in Figure 2 inductively defining the typing relation.

Case ($:_0$). $\Phi(\Gamma, \mathbf{0}, \text{nat})$ holds because $0 \triangleleft_{\text{nat}} \mathbf{0}$.

Case ($:_{\text{succ}}$). We have to prove that $\Phi(\Gamma, M, \text{nat})$ implies $\Phi(\Gamma, \text{succ}(M), \text{nat})$. But this follows from the easily verified fact that

$$d \triangleleft_{\text{nat}} M \Rightarrow s_{\perp}(d) \triangleleft_{\text{nat}} \text{succ}(M)$$

where $s_{\perp} : \mathbb{N}_{\perp} \rightarrow \mathbb{N}_{\perp}$ is the continuous function used in Section 6.2 to describe the denotation of successor terms, $\text{succ}(M)$.

Cases ($:_{\text{pred}}$) and ($:_{\text{zero}}$) are similar to the previous case.

Case ($:_{\text{bool}}$). $\Phi(\Gamma, \text{true}, \text{bool})$ holds because $\text{true} \triangleleft_{\text{bool}} \text{true}$. Similarly for $\Phi(\Gamma, \text{false}, \text{bool})$.

Case ($:_{\text{if}}$). It suffices to show that if $d_1 \triangleleft_{\text{bool}} M_1$, $d_2 \triangleleft_{\tau} M_2$, and $d_3 \triangleleft_{\tau} M_3$, then

$$(13) \quad \text{if}(d_1, (d_2, d_3)) \triangleleft_{\tau} \text{if } M_1 \text{ then } M_2 \text{ else } M_3$$

where if is the continuous function $:\mathbb{B}_{\perp} \times (\llbracket \tau \rrbracket \times \llbracket \tau \rrbracket) \rightarrow \llbracket \tau \rrbracket$ of Proposition 3.2.2 that was used in Section 6.2 to describe the denotation of conditional terms. If $d_1 = \perp \in \mathbb{B}_{\perp}$, then $\text{if}(d_1, (d_2, d_3)) = \perp$ and (13) holds by Lemma 7.2.1(i). So we may assume $d_1 \neq \perp$, in which case either $d_1 = \text{true}$ or $d_1 = \text{false}$. We consider the case $d_1 = \text{true}$; the argument for the other case is similar.

Since $\text{true} = d_1 \triangleleft_{\text{bool}} M_1$, by the definition of $\triangleleft_{\text{bool}}$ (Slide 64) we have $M_1 \Downarrow_{\text{bool}} \text{true}$. It follows from rule (\Downarrow_{if1}) in Figure 3 that

$$\forall V (M_2 \Downarrow_{\tau} V \Rightarrow \text{if } M_1 \text{ then } M_2 \text{ else } M_3 \Downarrow_{\tau} V).$$

So Lemma 7.2.1(iii) applied to $d_2 \triangleleft_{\tau} M_2$ yields that

$$d_2 \triangleleft_{\tau} \text{if } M_1 \text{ then } M_2 \text{ else } M_3$$

and then since $d_2 = \text{if}(\text{true}, (d_2, d_3)) = \text{if}(d_1, (d_2, d_3))$, we get (13), as required.

Case ($:_{\text{var}}$). $\Phi(\Gamma, x, \Gamma(x))$ holds because if $\rho \triangleleft_{\Gamma} \sigma$, then for all $x \in \text{dom}(\Gamma)$ we have $\llbracket \Gamma \vdash x \rrbracket(\rho) \stackrel{\text{def}}{=} \rho(x) \triangleleft_{\Gamma(x)} \sigma(x) \stackrel{\text{def}}{=} x[\sigma]$.

Case ($:_{\text{fn}}$). Suppose $\Phi(\Gamma[x \mapsto \tau], M, \tau')$ and $\rho \triangleleft_{\Gamma} \sigma$ hold. We have to show that $\llbracket \Gamma \vdash \text{fn } x : \tau . M \rrbracket(\rho) \triangleleft_{\tau \rightarrow \tau'} (\text{fn } x : \tau . M)[\sigma]$, i.e. that $d \triangleleft_{\tau} N$ implies

$$(14) \quad \llbracket \Gamma \vdash \text{fn } x : \tau . M \rrbracket(\rho)(d) \triangleleft_{\tau'} ((\text{fn } x : \tau . M)[\sigma])N.$$

From Slide 58 we have

$$(15) \quad \llbracket \Gamma \vdash \mathbf{fn} \ x : \tau . M \rrbracket(\rho)(d) = \llbracket \Gamma[x \mapsto \tau] \vdash M \rrbracket(\rho[x \mapsto d]).$$

Since $(\mathbf{fn} \ x : \tau . M)[\sigma] = \mathbf{fn} \ x : \tau . M[\sigma]$ and $(M[\sigma])[N/x] = M[\sigma[x \mapsto N]]$, by rule $(\Downarrow_{\text{cbn}})$ in Figure 3 we have

$$(16) \quad \forall V \ (M[\sigma[x \mapsto N]] \Downarrow_{\tau'} V \Rightarrow ((\mathbf{fn} \ x : \tau . M)[\sigma])N \Downarrow_{\tau'} V).$$

Since $\rho \triangleleft_{\Gamma} \sigma$ and $d \triangleleft_{\tau} N$, we have $\rho[x \mapsto d] \triangleleft_{\Gamma[x \mapsto \tau]} \sigma[x \mapsto N]$; so by $\Phi(\Gamma[x \mapsto \tau], M, \tau')$ we have

$$\llbracket \Gamma[x \mapsto \tau] \vdash M \rrbracket(\rho[x \mapsto d]) \triangleleft_{\tau'} M[\sigma[x \mapsto N]].$$

Then (14) follows from this by applying Lemma 7.2.1(iii) to (15) and (16).

Case ($:\text{app}$). It suffices to show that if $d_1 \triangleleft_{\tau \rightarrow \tau'} M_1$ and $d_2 \triangleleft_{\tau} M_2$, then $d_1(d_2) \triangleleft_{\tau'} M_1 M_2$. But this follows immediately from the definition of $\triangleleft_{\tau \rightarrow \tau'}$.

Case ($:\text{fix}$). Suppose $\Phi(\Gamma, M, \tau \rightarrow \tau)$ holds. For any $\rho \triangleleft_{\Gamma} \sigma$, we have to prove that

$$(17) \quad \llbracket \Gamma \vdash \mathbf{fix}(M) \rrbracket(\rho) \triangleleft_{\tau} \mathbf{fix}(M)[\sigma].$$

Referring to Slide 58, we have $\llbracket \Gamma \vdash \mathbf{fix}(M) \rrbracket(\rho) = \text{fix}(f)$, where $f \stackrel{\text{def}}{=} \llbracket \Gamma \vdash M \rrbracket(\rho)$. By Lemma 7.2.1(ii)

$$S \stackrel{\text{def}}{=} \{d \mid d \triangleleft_{\tau} \mathbf{fix}(M)[\sigma]\}$$

is an admissible subset of the domain $\llbracket \tau \rrbracket$. So by Scott's Fixed Point Induction Principle (Slide 40) to prove (17) it suffices to prove

$$\forall d \in \llbracket \tau \rrbracket \ (d \in S \Rightarrow f(d) \in S).$$

Now since $\rho \triangleleft_{\Gamma} \sigma$, by $\Phi(\Gamma, M, \tau \rightarrow \tau)$ and by definition of f we have $f \triangleleft_{\tau \rightarrow \tau} M[\sigma]$. So if $d \in S$, i.e. $d \triangleleft_{\tau} \mathbf{fix}(M)[\sigma]$, then by definition of $\triangleleft_{\tau \rightarrow \tau}$, it is the case that

$$(18) \quad f(d) \triangleleft_{\tau} (M[\sigma])(\mathbf{fix}(M)[\sigma]).$$

Rule $(\Downarrow_{\text{fix}})$ in Figure 3 implies

$$(19) \quad \forall V \ ((M[\sigma])(\mathbf{fix}(M)[\sigma]) \Downarrow_{\tau} V \Rightarrow \mathbf{fix}(M)[\sigma] \Downarrow_{\tau} V).$$

Then applying Lemma 7.2.1(iii) to (18) and (19) yields $f(d) \triangleleft_{\tau} \mathbf{fix}(M)[\sigma]$, i.e. $f(d) \in S$, as required. \square

7.3 Extensionality

Recall the notion of contextual equivalence of PCF terms from Slide 47. The *contextual preorder* is the one-sided version of this relation defined on Slide 67. Clearly

$$\Gamma \vdash M_1 \cong_{\text{ctx}} M_2 : \tau \Leftrightarrow (\Gamma \vdash M_1 \leq_{\text{ctx}} M_2 : \tau \ \& \ \Gamma \vdash M_2 \leq_{\text{ctx}} M_1 : \tau).$$

As usual we write $M_1 \leq_{\text{ctx}} M_2 : \tau$ for $\emptyset \vdash M_1 \leq_{\text{ctx}} M_2 : \tau$ in case M_1 and M_2 are closed terms.

The formal approximation relations \triangleleft_τ actually characterise the PCF contextual preorder between closed terms, in the sense shown on Slide 68.

Contextual preorder between PCF terms

Given PCF terms M_1, M_2 , PCF type τ , and a type environment Γ , the relation $\Gamma \vdash M_1 \leq_{\text{ctx}} M_2 : \tau$ is defined to hold iff

- Both the typings $\Gamma \vdash M_1 : \tau$ and $\Gamma \vdash M_2 : \tau$ hold.
- For all PCF contexts \mathcal{C} for which $\mathcal{C}[M_1]$ and $\mathcal{C}[M_2]$ are closed terms of type γ , *where* $\gamma = \text{nat}$ or $\gamma = \text{bool}$, and for all values $V : \gamma$,

$$\mathcal{C}[M_1] \Downarrow_\gamma V \Rightarrow \mathcal{C}[M_2] \Downarrow_\gamma V.$$

Slide 67

Contextual preorder from formal approximation

Proposition. For all PCF types τ and all closed terms $M_1, M_2 \in \text{PCF}_\tau$

$$M_1 \leq_{\text{ctx}} M_2 : \tau \Leftrightarrow \llbracket M_1 \rrbracket \triangleleft_\tau M_2.$$

Slide 68

Proof of the Proposition on Slide 68. It is not hard to prove that for closed terms $M_1, M_2 \in \text{PCF}_\tau$, $M_1 \leq_{\text{ctx}} M_2 : \tau$ holds if and only if for all $M \in \text{PCF}_{\tau \rightarrow \text{bool}}$

$$M M_1 \Downarrow_{\text{bool}} \mathbf{true} \Rightarrow M M_2 \Downarrow_{\text{bool}} \mathbf{true}.$$

Now if $\llbracket M_1 \rrbracket \triangleleft_\tau M_2$, then for any $M \in \text{PCF}_{\tau \rightarrow \text{bool}}$ since by the Fundamental Property of \triangleleft we have $\llbracket M \rrbracket \triangleleft_{\tau \rightarrow \text{bool}} M$, the definition of $\triangleleft_{\tau \rightarrow \text{bool}}$ implies that

$$(20) \quad \llbracket M M_1 \rrbracket = \llbracket M \rrbracket(\llbracket M_1 \rrbracket) \triangleleft_{\text{bool}} M M_2.$$

So if $M M_1 \Downarrow_{\text{bool}} \mathbf{true}$, then $\llbracket M M_1 \rrbracket = \mathbf{true}$ (by the Soundness property) and hence by definition of $\triangleleft_{\text{bool}}$ from (20) we get $M M_2 \Downarrow_{\text{bool}} \mathbf{true}$. Thus using the characterisation of \leq_{ctx} mentioned above, we have $M_1 \leq_{\text{ctx}} M_2 : \tau$.

This establishes the right-to-left implication on Slide 68. For the converse, it is enough to prove

$$(21) \quad (d \triangleleft_\tau M_1 \ \& \ M_1 \leq_{\text{ctx}} M_2 : \tau) \Rightarrow d \triangleleft_\tau M_2.$$

For then if $M_1 \leq_{\text{ctx}} M_2 : \tau$, since $\llbracket M_1 \rrbracket \triangleleft_\tau M_1$ (by the Fundamental Property), (21) implies $\llbracket M_1 \rrbracket \triangleleft_\tau M_2$. Property (21) follows by induction on the structure of the type τ , using the following easily verified properties of \leq_{ctx} :

- If $\tau = \text{nat}$ or bool , then $M_1 \leq_{\text{ctx}} M_2 : \tau$ implies

$$\forall V : \tau (M_1 \Downarrow_{\tau} V \Rightarrow M_2 \Downarrow_{\tau} V).$$

- If $M_1 \leq_{\text{ctx}} M_2 : \tau \rightarrow \tau'$, then $M_1 M \leq_{\text{ctx}} M_2 M : \tau'$, for all $M : \tau$.

□

The bi-implication on Slide 68 allows us to transfer the extensionality properties enjoyed by the domain partial orders \sqsubseteq to the contextual preorder, as shown on Slide 69. (These kind of properties of PCF were first proved by Milner 1977, First Context Lemma, page 6.)

Extensionality properties of \leq_{ctx}

For $\tau = \text{bool}$ or nat , $M_1 \leq_{\text{ctx}} M_2 : \tau$ holds if and only if

$$\forall V : \tau (M_1 \Downarrow_{\tau} V \Rightarrow M_2 \Downarrow_{\tau} V).$$

At a function type $\tau \rightarrow \tau'$, $M_1 \leq_{\text{ctx}} M_2 : \tau \rightarrow \tau'$ holds if and only if

$$\forall M : \tau (M_1 M \leq_{\text{ctx}} M_2 M : \tau').$$

Slide 69

Proof of the properties on Slide 69. The ‘only if’ directions are easy consequences of the definition of \leq_{ctx} .

For the ‘if’ direction in case $\tau = \text{bool}$ or nat , we have

$$\begin{aligned} \llbracket M_1 \rrbracket = \llbracket V \rrbracket &\Rightarrow M_1 \Downarrow_{\tau} V && \text{by the adequacy property} \\ &\Rightarrow M_2 \Downarrow_{\tau} V && \text{by assumption} \end{aligned}$$

and hence $\llbracket M_1 \rrbracket \triangleleft_{\tau} M_2$ by definition of \triangleleft at these ground types. Now apply the Proposition on Slide 68.

For the ‘if’ direction in case of a function type $\tau \rightarrow \tau'$, we have

$$\begin{aligned} d \triangleleft_{\tau} M &\Rightarrow \llbracket M_1 \rrbracket(d) \triangleleft_{\tau'} M_1 M && \text{since } \llbracket M_1 \rrbracket \triangleleft_{\tau} M_1 \\ &\Rightarrow \llbracket M_1 \rrbracket(d) \triangleleft_{\tau'} M_2 M && \text{by (21), since } M_1 M \leq_{\text{ctx}} M_2 M : \tau' \\ &&& \text{by assumption} \end{aligned}$$

and hence $\llbracket M_1 \rrbracket \triangleleft_{\tau \rightarrow \tau'} M_2$ by definition of \triangleleft at type $\tau \rightarrow \tau'$. So once again we can apply the Proposition on Slide 68 to get the desired conclusion. \square

7.4 Exercises

Exercise 7.4.1. For any PCF type τ and any closed terms $M_1, M_2 \in \text{PCF}_{\tau}$, show that

$$(22) \quad \forall V : \tau \ (M_1 \Downarrow_{\tau} V \Leftrightarrow M_2 \Downarrow_{\tau} V) \Rightarrow M_1 \cong_{\text{ctx}} M_2 : \tau.$$

[Hint: combine the Proposition on Slide 68 with Lemma 7.2.1(iii).]

Exercise 7.4.2. Use (22) to show that β -conversion is valid up to contextual equivalence in PCF, in the sense that for all $\mathbf{fn} \ x : \tau . M_1 \in \text{PCF}_{\tau \rightarrow \tau'}$ and $M_2 \in \text{PCF}_{\tau}$

$$(\mathbf{fn} \ x : \tau . M_1) M_2 \cong_{\text{ctx}} M_1[M_2/x] : \tau'.$$

Exercise 7.4.3. Is the converse of (22) valid at all types? [Hint: recall the extensionality property of \leq_{ctx} at function types (Slide 69) and consider the terms $\mathbf{fix}(\mathbf{fn} \ f : (\text{nat} \rightarrow \text{nat}) . f)$ and $\mathbf{fn} \ x : \text{nat} . \mathbf{fix}(\mathbf{fn} \ x' : \text{nat} . x')$ of type $\text{nat} \rightarrow \text{nat}$.]

8 Full Abstraction

8.1 Failure of full abstraction

As we saw on Slide 49, the adequacy property implies that contextual equivalence of two PCF terms can be proved by showing that they have equal denotations: $\llbracket M_1 \rrbracket = \llbracket M_2 \rrbracket \in \llbracket \tau \rrbracket \Rightarrow M_1 \cong_{\text{ctx}} M_2 : \tau$. Unfortunately the converse is false: *there are contextually equivalence PCF terms with unequal denotations.*

Proof principle

For all types τ and closed terms $M_1, M_2 \in \text{PCF}_\tau$,

$$\llbracket M_1 \rrbracket = \llbracket M_2 \rrbracket \text{ in } \llbracket \tau \rrbracket \implies M_1 \cong_{\text{ctx}} M_2 : \tau .$$

Hence, to prove

$$M_1 \cong_{\text{ctx}} M_2 : \tau$$

it suffices to establish

$$\llbracket M_1 \rrbracket = \llbracket M_2 \rrbracket \text{ in } \llbracket \tau \rrbracket .$$

Slide 70

Full abstraction

A denotational model is said to be *fully abstract* whenever denotational equality characterises contextual equivalence.

- ▶ The domain model of PCF is *not* fully abstract.

In other words, there are contextually equivalent PCF terms with different denotations.

Slide 71

In general one says that a denotational semantics is *fully abstract* if contextual equivalence coincides with equality of denotation. Thus the denotational semantics of PCF using domains and continuous functions fails to be fully abstract. The classic example demonstrating this failure is due to Plotkin (1977) and involves the *parallel-or* function shown on Slide 72.

Parallel-or function

is the continuous function $por : \mathbb{B}_\perp \rightarrow (\mathbb{B}_\perp \rightarrow \mathbb{B}_\perp)$ defined by

<i>por</i>	<i>true</i>	<i>false</i>	\perp
<i>true</i>	<i>true</i>	<i>true</i>	<i>true</i>
<i>false</i>	<i>true</i>	<i>false</i>	\perp
\perp	<i>true</i>	\perp	\perp

Slide 72

Contrast por with the ‘sequential-or’ function shown on Slide 73. Both functions give the usual boolean ‘or’ function when restricted to $\{true, false\}$, but differ in their behaviour at arguments involving the element \perp denoting ‘non-termination’. Note that $por(d_1, d_2) = true$ if *either* of d_1 or d_2 is *true*, even if the other argument is \perp ; whereas $orelse(d_1, d_2) = true$ implies $d_1 \neq \perp$.

Left sequential-or function

The function $orelse : \mathbb{B}_\perp \rightarrow (\mathbb{B}_\perp \rightarrow \mathbb{B}_\perp)$ defined by

<i>orelse</i>	<i>true</i>	<i>false</i>	\perp
<i>true</i>	<i>true</i>	<i>true</i>	<i>true</i>
<i>false</i>	<i>true</i>	<i>false</i>	\perp
\perp	\perp	\perp	\perp

is the denotation of the PCF term

fn $x : bool . \mathbf{fn}$ $x' : bool . \mathbf{if}$ x **then** **true** **else** x'

of type $bool \rightarrow (bool \rightarrow bool)$.

Slide 73

As noted on Slide 73, *orelse* can be defined in PCF, in the sense that there is a closed PCF term $M : bool \rightarrow (bool \rightarrow bool)$ with $\llbracket M \rrbracket = orelse$. This term M tests whether its first argument is **true** or **false** (and so diverges if that first argument diverges), in the first case returning **true** (leaving the second argument untouched) and in the second case returning the second argument. By contrast, for *por* we have the Proposition stated on Slide 74. We will not give the proof of this proposition here. Plotkin (1977) proves it via an ‘Activity Lemma’, but there are alternative approaches using ‘stable’ continuous functions (Gunter 1992, p 181), or using ‘sequential logical relations’ (Sieber 1992). The key idea is that evaluation in PCF proceeds *sequentially*. So whatever P is, evaluation of $P M_1 M_2$ must at some point involve full evaluation of either M_1 or M_2 (P cannot ignore its arguments if it is to return **true** in some cases and **false** in others); whereas an algorithm to compute *por* at a pair of arguments must compute the values of those arguments ‘in parallel’ in case one diverges whilst the other yields the value *true*.

One can exploit the undefinability of *por* in PCF to manufacture a pair of contextually equivalent closed terms in PCF with unequal denotations. Such a pair is given on Slide 75.

Undeifiability of parallel-or

Proposition. *There is no closed PCF term*

$$P : \text{bool} \rightarrow (\text{bool} \rightarrow \text{bool})$$

satisfying

$$\llbracket P \rrbracket = \text{por} : \mathbb{B}_\perp \rightarrow (\mathbb{B}_\perp \rightarrow \mathbb{B}_\perp) .$$

Slide 74

Parallel-or test functions

For $i = 1, 2$ define

$$\begin{aligned}
 T_i &\stackrel{\text{def}}{=} \mathbf{fn} f : \text{bool} \rightarrow (\text{bool} \rightarrow \text{bool}) . \\
 &\quad \mathbf{if} (f \text{ true } \Omega) \mathbf{then} \\
 &\quad \quad \mathbf{if} (f \Omega \text{ true}) \mathbf{then} \\
 &\quad \quad \quad \mathbf{if} (f \text{ false false}) \mathbf{then} \Omega \text{ else } B_i \\
 &\quad \quad \quad \mathbf{else} \Omega \\
 &\quad \mathbf{else} \Omega
 \end{aligned}$$

where $B_1 \stackrel{\text{def}}{=} \text{true}$, $B_2 \stackrel{\text{def}}{=} \text{false}$,
and $\Omega \stackrel{\text{def}}{=} \mathbf{fix}(\mathbf{fn} x : \text{bool} . x)$.

Slide 75

Failure of full abstraction

Proposition.

$$T_1 \cong_{\text{ctx}} T_2 : (\text{bool} \rightarrow (\text{bool} \rightarrow \text{bool})) \rightarrow \text{bool}$$

$$\llbracket T_1 \rrbracket \neq \llbracket T_2 \rrbracket \in (\mathbb{B}_\perp \rightarrow (\mathbb{B}_\perp \rightarrow \mathbb{B}_\perp)) \rightarrow \mathbb{B}_\perp$$

Slide 76

Proof of the Proposition on slide 76. From the definition of por on Slide 72 and the definition of $\llbracket - \rrbracket$ in Section 6.2, it is not hard to see that

$$\llbracket T_i \rrbracket(por) = \begin{cases} true & \text{if } i = 1 \\ false & \text{if } i = 2. \end{cases}$$

Thus $\llbracket T_1 \rrbracket(por) \neq \llbracket T_2 \rrbracket(por)$ and therefore $\llbracket T_1 \rrbracket \neq \llbracket T_2 \rrbracket$.

To see that $T_1 \cong_{\text{ctx}} T_2 : (\text{bool} \rightarrow (\text{bool} \rightarrow \text{bool})) \rightarrow \text{bool}$ we use the extensionality results on Slide 69. Thus we have to show for all $M : \text{bool} \rightarrow (\text{bool} \rightarrow \text{bool})$ and $V \in \{\text{true}, \text{false}\}$ that

$$(23) \quad T_1 M \Downarrow_{\text{bool}} V \Leftrightarrow T_2 M \Downarrow_{\text{bool}} V.$$

But the definition of T_i is such that $T_i M \Downarrow_{\text{bool}} V$ only holds if

$$M \text{ true } \Omega \Downarrow_{\text{bool}} \text{true}, M \Omega \text{ true} \Downarrow_{\text{bool}} \text{true}, M \text{ false false} \Downarrow_{\text{bool}} \text{false}.$$

By the soundness property of Slide 48 this means that

$$\llbracket M \rrbracket(true)(\perp) = true, \llbracket M \rrbracket(\perp)(true) = true, \llbracket M \rrbracket(false)(false) = false.$$

(Recall from Exercise 6.5.2 that $\llbracket \Omega \rrbracket = \perp$.) It follows in that case that the continuous function $\llbracket M \rrbracket : (\mathbb{B}_\perp \times \mathbb{B}_\perp) \rightarrow \mathbb{B}_\perp$ coincides with por (see Exercise 8.4.1). But this is impossible, by the Proposition on Slide 74. Therefore (23) is trivially satisfied for all M , and thus T_1 and T_2 are indeed contextually equivalent. \square

8.2 PCF+por

The failure of full abstraction for the denotational semantics of PCF can be repaired by extending PCF with extra terms for those elements of the domain-theoretic model that are not definable in the language as originally given. We have seen that *por* is one such element ‘missing’ from PCF, and one of the remarkable results in (Plotkin 1977) is that this is the only thing we need add to PCF to obtain full abstraction. This is stated without proof on Slides 77 and 78.

PCF+por	
<i>Expressions</i>	$M ::= \dots \mid \mathbf{por}(M, M)$
<i>Typing</i>	$\frac{\Gamma \vdash M_1 : \mathit{bool} \quad \Gamma \vdash M_2 : \mathit{bool}}{\Gamma \vdash \mathbf{por}(M_1, M_2) : \mathit{bool}}$
<i>Evaluation</i>	$\frac{M_1 \Downarrow_{\mathit{bool}} \mathbf{true}}{\mathbf{por}(M_1, M_2) \Downarrow_{\mathit{bool}} \mathbf{true}} \quad \frac{M_2 \Downarrow_{\mathit{bool}} \mathbf{true}}{\mathbf{por}(M_1, M_2) \Downarrow_{\mathit{bool}} \mathbf{true}}$ $\frac{M_1 \Downarrow_{\mathit{bool}} \mathbf{false} \quad M_2 \Downarrow_{\mathit{bool}} \mathbf{false}}{\mathbf{por}(M_1, M_2) \Downarrow_{\mathit{bool}} \mathbf{false}}$

Slide 77

Plotkin's full abstraction result

The denotational semantics of PCF+por terms is given by extending the definition on Slides 55–59 with the clause

$$\llbracket \Gamma \vdash \mathbf{por}(M_1, M_2) \rrbracket(\rho) \stackrel{\text{def}}{=} \mathit{por}(\llbracket \Gamma \vdash M_1 \rrbracket(\rho))(\llbracket \Gamma \vdash M_2 \rrbracket(\rho))$$

where $\mathit{por} : \mathbb{B}_\perp \rightarrow (\mathbb{B}_\perp \rightarrow \mathbb{B}_\perp)$ is as on Slide 72.

This denotational semantics is fully abstract for contextual equivalence of PCF+por terms:

$$\Gamma \vdash M_1 \cong_{\text{ctx}} M_2 : \tau \Leftrightarrow \llbracket \Gamma \vdash M_1 \rrbracket = \llbracket \Gamma \vdash M_2 \rrbracket.$$

Slide 78

8.3 Fully abstract semantics for PCF

The evaluation of PCF terms involves a form of ‘sequentiality’ which is not reflected in the denotational semantics of PCF using domains and continuous functions: the continuous function por does not denote any PCF term and this results in a mismatch between denotational equality and contextual equivalence. But what precisely does ‘sequentiality’ mean in general? Can we characterise it in an abstract way, independent of the particular syntax of PCF terms, and hence give a more refined form of denotational semantics that *is* fully abstract for contextual equivalence for PCF (and for other types of language besides the simple, pure functional language PCF)? These questions have motivated the development much domain theory and denotational semantics since the appearance of (Plotkin 1977): see the survey by Ong (1995), for example.

It is only recently that definitive answers have emerged even for such an apparently simple language as PCF. O’Hearn and Riecke (1995) construct a fully abstract model of PCF by using certain kinds of ‘logical relation’ to repair the deficiencies of the standard model we have described here. Although this does provide a solution, it does not seem to give much insight into the nature of sequential computation. By contrast, Abramsky, Jagadeesan, and Malacaria (2000) and Hyland and Ong (2000) solve the problem by introducing what appears to be a radically different approach to giving semantics to programming languages (not just PCF),

based upon certain kinds of two-player game: see (Abramsky 1997) and (Hyland 1997) for introductions to this ‘game semantics’.

Finally, a negative result by Loader should be mentioned. Note that the material in Section 8.1 does not depend upon the presence of numbers and arithmetic in PCF. Let PCF_2 denote the fragment of PCF only involving *bool* and the function types formed from it, **true**, **false**, conditionals, variables, function abstraction and application, and a divergent term $\Omega_{\text{bool}} : \text{bool}$. Since \mathbb{B}_\perp is a finite domain and since the function domain formed from finite domains is again finite, the domain associated to each PCF_2 type is finite.¹ The domain model is adequate for PCF_2 and hence there are only finitely many different PCF_2 terms of each type, up to contextual equivalence. Given these finiteness properties, and the terribly simple nature of the language, one might hope that the following questions are decidable (uniformly in the PCF_2 type τ):

- Which elements of $\llbracket \tau \rrbracket$ are definable by PCF_2 terms?
- When are two PCF_2 of type τ contextually equivalent?

Quite remarkably Loader (2001) shows that these are recursively undecidable questions.

8.4 Exercises

Exercise 8.4.1. Suppose that a monotonic function $p : (\mathbb{B}_\perp \times \mathbb{B}_\perp) \rightarrow \mathbb{B}_\perp$ satisfies

$$p(\text{true}, \perp) = \text{true}, \quad p(\perp, \text{true}) = \text{true}, \quad \text{and} \quad p(\text{false}, \text{false}) = \text{false}.$$

Show that p coincides with the parallel-or function on Slide 72 in the sense that $p(d_1, d_2) = \text{por}(d_1)(d_2)$, for all $d_1, d_2 \in \mathbb{B}_\perp$.

Exercise 8.4.2. Show that even though there are two evaluation rules on Slide 77 with conclusion $\text{por}(M_1, M_2) \Downarrow_{\text{bool}} \text{true}$, nevertheless the evaluation relation for $\text{PCF}+\text{por}$ is still deterministic (in the sense of Proposition 5.4.1).

Exercise 8.4.3. Give the axioms and rules for an inductively defined transition relation for $\text{PCF}+\text{por}$. This should take the form of a binary relation $M \rightarrow M'$ between closed $\text{PCF}+\text{por}$ terms. It should satisfy

$$M \Downarrow V \Leftrightarrow M \rightarrow^* V$$

(where \rightarrow^* is the reflexive-transitive closure of \rightarrow).

¹A further simplification arises from the fact that if the domains D and D' are finite, then they contain no non-trivial chains and hence the continuous functions $D \rightarrow D'$ are just the monotone functions.
