Program Verification

Techniques for specifying and verifying program properties:

- **Specification:** precise statement of program properties in first-order logic. Also called program annotations.
 - ▶ Partial correctness properties
 - ▶ Total correctness properties
- **Verification methods:** for proving partial/total correctness
 - ▶ Inductive assertion method
 - ▶ Ranking function method

Running Example 1: Linear Search

```
bool LinearSearch (int a[], int l, int u, int e) {  
    int i := l;  
    while (i ≤ u) {  
        if (a[i] = e) return true  
        i := i + 1;  
    }  
    return false  
}
```

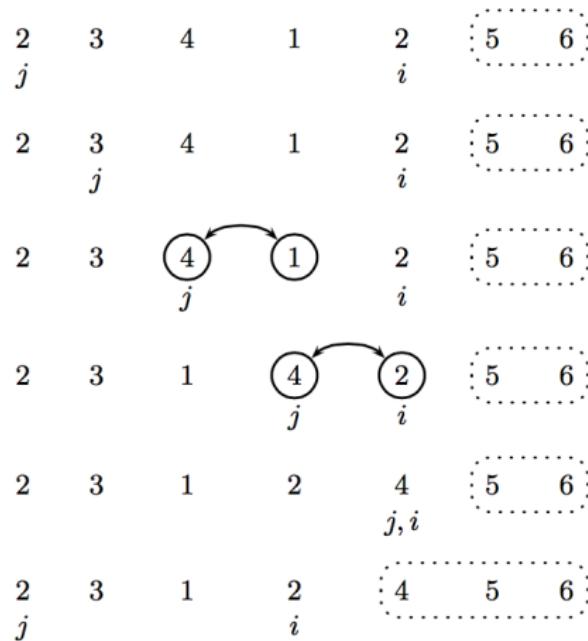

Running Example 2: Binary Search

```
bool BinarySearch (int a[], int l, int u, int e) {  
    if (l > u) return false;  
    else {  
        int m := (l + u) div 2;  
        if (a[m] = e) return true;  
        else if (a[m] < e) return BinarySearch (a, m + 1, u, e)  
        else return BinarySearch (a, l, m - 1, e)  
    }  
}
```

Running Example 3: Bubble Sort

```
bool BubbleSort (int a[]) {  
    int[] a := a0  
    for (int i := |a| - 1; i > 0; i := i - 1) {  
        for (int j := 0; j < i; j := j + 1) {  
            if (a[j] > a[j + 1]) {  
                int t := a[j];  
                int a[j] := a[j + 1];  
                int a[j + 1] := t;  
            }  
        }  
    }  
    return a;  
}
```

Running Example 3: Bubble Sort

Specification

- An annotation is a first-order logic formula F .
- An annotation F at location L expresses an *invariant* asserting that F is true whenever program control reaches L .
- Three types of annotations:
 - ▶ **Function specification**
 - ▶ **Loop invariant**
 - ▶ **Assertion**

Function Specifications

Formulas whose free variables include only the formal parameters and return variables.

- Precondition: Specification about what should be true upon entering the function.
- Postcondition: Specification about the expected output of the function. Postcondition relates the input and output of the function.

Example: Linear Search

The behavior of LinearSearch:

- It behaves correctly only when $l \geq 0$ and $u < |a|$.
- It returns true iff the array a contains the value e in the range $[l, u]$.

```
@pre : 0 ≤ l ∧ u < |a|
@post : rv ↔ ∃i. l ≤ i ≤ u ∧ a[i] = e
bool LinearSearch (int a[], int l, int u, int e) {
    int i := l;
    while (i ≤ u) {
        if (a[i] = e) return true
        i := i + 1;
    }
    return false
}
```

Our goal is to prove the *partial correctness* property: if the function precondition holds and the function halts, then the function postcondition holds upon return.

Example: Binary Search

- It behaves correctly only when $l \geq 0$, $u < |a|$, and a is sorted.
- It returns true iff the array a contains the value e in the range $[l, u]$.

$\text{@pre : } 0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$

$\text{@post : } rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$

```
bool BinarySearch (int a[], int l, int u, int e) {
```

```
    if ( $l > u$ ) return false;
```

```
    else {
```

```
        int m := ( $l + u$ ) div 2;
```

```
        if ( $a[m] = e$ ) return true;
```

```
        else if ( $a[m] < e$ ) return BinarySearch ( $a, m + 1, u, e$ )
```

```
        else return BinarySearch ( $a, l, m - 1, e$ )
```

```
}
```

```
}
```

$\text{sorted}(a, l, u) \iff \forall i, j. l \leq i \leq j \leq u \rightarrow a[i] \leq a[j]$

Example: Bubble Sort

- Any array can be given.
- The returned array is sorted.

```
@pre : T
@post : sorted(rv, 0, |rv| - 1)
bool BubbleSort (int a[]) {
    int[] a := a0
    for (int i := |a| - 1; i > 0; i := i - 1) {
        for (int j := 0; j < i; j := j + 1) {
            if (a[j] > a[j + 1]) {
                int t := a[j];
                int a[j] := a[j + 1];
                int a[j + 1] := t;
            }
        }
    }
    return a;
}
```

Loop Invariants

For proving partial correctness, each loop must be annotated with a loop invariant F :

```
while  
  @F  
  ((condition)) {  
    body  
  }
```

Loop invariant is a property that is preserved by executions of the loop body; F holds at the beginning of every iteration. Therefore,

- $F \wedge \langle \text{condition} \rangle$ holds on entering the body.
- $F \wedge \neg\langle \text{condition} \rangle$ holds when exiting the loop.

Loop Invariants

Find a loop invariant of the loop in LinearSearch:

```
@pre : 0 ≤ l ∧ u < |a|
@post : rv ↔ ∃i.l ≤ i ≤ u ∧ a[i] = e
bool LinearSearch (int a[], int l, int u, int e) {
    int i := l;
    while
        @L : l ≤ i ∧ (∀j. l ≤ j < i → a[j] ≠ e)
        (i ≤ u) {
            if (a[i] = e) return true
            i := i + 1;
        }
    return false
}
```

Example: Bubble Sort

```
@pre : ⊤
@post : sorted(rv, 0, |rv| - 1)
bool BubbleSort (int a[]) {
    int[] a := a₀
    @L₁ [ −1 ≤ i < |a|
          ∧ partitioned(a, 0, i, i + 1, |a| - 1)
          ∧ sorted(a, i, |a| - 1) ]
    for (int i := |a| - 1; i > 0; i := i - 1) {
        @L₂ [ 1 ≤ i < |a| ∧ 0 ≤ j ≤ i
              ∧ partitioned(a, 0, i, i + 1, |a| - 1)
              ∧ partitioned(a, 0, j - 1, j, j)
              ∧ sorted(a, i, |a| - 1) ]
        for (int j := 0; j < i; j := j + 1) {
            if (a[j] > a[j + 1]) {
                int t := a[j];
                int a[j] := a[j + 1];
                int a[j + 1] := t;
            }
        }
    }
    return a;
}
```

$$\text{partitioned}(a, l_1, u_1, l_2, u_2) \iff \forall i, j. l_1 \leq i \leq u_1 < l_2 \leq j \leq u_2 \rightarrow a[i] \leq a[j].$$

Assertions

- Programmers' formal comments on the program behavior
- Runtime assertions: division by 0, array out of bounds, etc

$\text{@pre : } 0 \leq l \wedge u < |a|$

$\text{@post : } rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$

bool LinearSearch (int $a[]$, int l , int u , int e) {

 int $i := l$;

 while

$\text{@L : } l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$

 ($i \leq u$) {

@0 \leq i < |a|

 if ($a[i] = e$) return true

$i := i + 1$;

 }

 return false

}

Proving Partial Correctness

- A function is *partially correct* if when the function's precondition is satisfied on entry, its postcondition is satisfied when the function returns (if it ever does).
- Inductive assertion method for proving partial correctness
 - ▶ Derive verification conditions (VCs) from a function.
 - ▶ Check the validity of VCs by an SMT solver.
 - ▶ If all of VCs are valid, the function is partially correct.

Deriving VCs

Done in two steps:

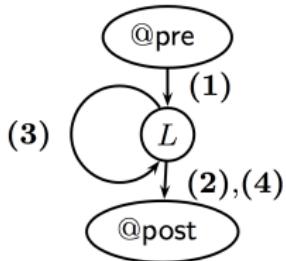

- The function is broken down into a finite set of *basic paths*.
- Each basic path generates a verification condition.
- Loops and recursive functions complicate proofs as they create unbounded number of paths. For loops, loop invariants cut the paths into a finite set of basic paths. For recursion, function specification cuts the paths.

Basic Paths

- A basic path is a sequence of atomic statements that begins at the function precondition or a loop invariant and ends at a loop invariant or the function postcondition.
- Moreover, a loop invariant can only occur at the beginning or the ending of a basic path (Basic paths do not cross loops).

Example: LinearSearch

```
@pre :  $0 \leq l \wedge u < |a|$ 
@post :  $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$ 
bool LinearSearch (int a[], int l, int u, int e) {
    int i := l;
    while
        @L :  $l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$ 
        ( $i \leq u$ ) {
            if ( $a[i] = e$ ) return true
            i := i + 1;
        }
    return false
}
```

(1)

@pre : $0 \leq l \wedge u < |a|$

$i := l;$

@L : $l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$

(2)

@L : $l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$

assume $i \leq u$;

assume $a[i] = e$;

$rv := \text{true}$

@post : $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$

(3)

@L : $l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$

assume $i \leq u$;

assume $a[i] \neq e$

$i := i + 1$;

@L : $l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$

(4)

@L : $l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$

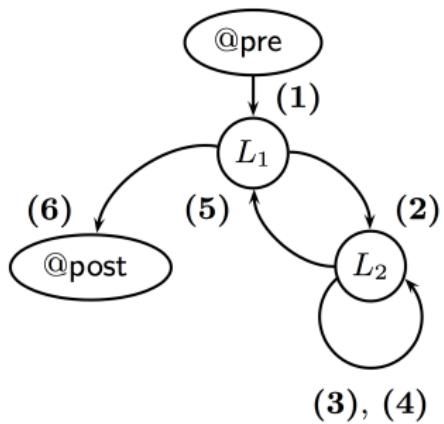

assume $i > u$;

$rv := \text{false}$

@post : $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$

Example: Bubble Sort

```
@pre : ⊤
@post : sorted(rv, 0, |rv| - 1)
bool BubbleSort (int a[]) {
    int[] a := a₀
    @L₁ [  $-1 \leq i < |a|$ 
           $\wedge \text{partitioned}(a, 0, i, i + 1, |a| - 1)$ 
           $\wedge \text{sorted}(a, i, |a| - 1)$  ]
    for (int i := |a| - 1; i > 0; i := i - 1) {
        @L₂ [  $1 \leq i < |a| \wedge 0 \leq j \leq i$ 
               $\wedge \text{partitioned}(a, 0, i, i + 1, |a| - 1)$ 
               $\wedge \text{partitioned}(a, 0, j - 1, j, j)$ 
               $\wedge \text{sorted}(a, i, |a| - 1)$  ]
        for (int j := 0; j < i; j := j + 1) {
            if (a[j] > a[j + 1]) {
                int t := a[j];
                int a[j] := a[j + 1];
                int a[j + 1] := t;
            }
        }
    }
    return a;
}
```

Basic Paths

(6)

$\text{@}L_1 : -1 \leq i < |a| \wedge \text{partitioned}(a, 0, i, i + 1, |a| - 1) \wedge \text{sorted}(a, i, |a| - 1)$

assume $i \leq 0$;

$rv := a$;

$\text{@post sorted}(rv, 0, |rv| - 1)$

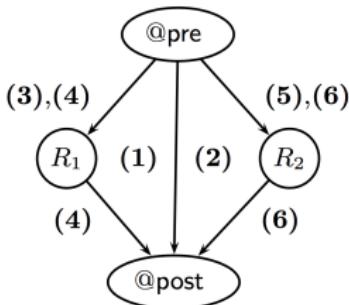

Basic Paths: Function Calls

- Both loops and (recursive) function calls may create an unbounded number of paths. For loops, loop invariants cut loops to produce a finite number of basic paths. For function calls, we use function specifications to cut calls.
- Observe that the postcondition of a function summarizes the effects of calling the function, as it relates the return variable and the formal parameters. So we can use these summaries to replace function calls.
- However, note that the function postcondition holds only when the precondition is satisfied on entry. To ensure this, we generate an extra basic path that asserts the precondition, called function call assertion.

Example: Binary Search

```
@pre :  $0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$ 
@post :  $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$ 
bool BinarySearch (int a[], int l, int u, int e) {
    if ( $l > u$ ) return false;
    else {
        int m := ( $l + u$ ) div 2;
        if ( $a[m] = e$ ) return true;
        else if ( $a[m] < e$ ) {
            @R1 :  $0 \leq m + 1 \wedge u < |a| \wedge \text{sorted}(a, m + 1, u)$ 
            return BinarySearch (a, m + 1, u, e)
        } else {
            @R2 :  $0 \leq l \wedge m - 1 < |a| \wedge \text{sorted}(a, l, m - 1)$ 
            return BinarySearch (a, l, m - 1, e)
        }
    }
}
```

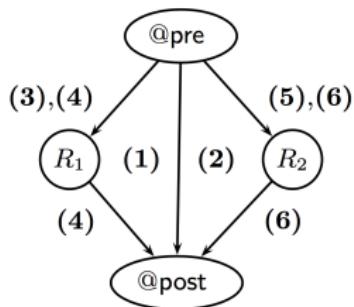

Basic Paths

- (1) $\text{@pre } 0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$
assume $l > u$;
 $rv := \text{false}$;
@post $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$
- (2) $\text{@pre } 0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$
assume $l \leq u$;
 $m := (l + u) \text{ div } 2$;
assume $a[m] = e$;
 $rv := \text{true}$;
@post $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$
- (3) $\text{@pre } 0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$
assume $l \leq u$;
 $m := (l + u) \text{ div } 2$;
assume $a[m] \neq e$;
assume $a[m] < e$;
 $\text{@}R_1 : 0 \leq m + 1 \wedge u < |a| \wedge \text{sorted}(a, m + 1, u)$
- (5) $\text{@pre } 0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$
assume $l \leq u$;
 $m := (l + u) \text{ div } 2$;
assume $a[m] \neq e$;
assume $a[m] \geq e$;
 $\text{@}R_2 : 0 \leq l \wedge m - 1 < |a| \wedge \text{sorted}(a, l, m - 1)$

Basic Paths

The basic paths that pass through function calls:

- (4) $\text{@pre } 0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$
assume $l \leq u$;
 $m := (l + u) \text{ div } 2$;
assume $a[m] \neq e$;
assume $a[m] < e$;
assume $v_1 \leftrightarrow \exists i. m + 1 \leq i \leq u \wedge a[i] = e$
 $rv := v_1$;
@post : $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$ ~~Let~~ e
- (6) $\text{@pre } 0 \leq l \wedge u < |a| \wedge \text{sorted}(a, l, u)$
assume $l \leq u$;
 $m := (l + u) \text{ div } 2$;
assume $a[m] \neq e$;
assume $a[m] \geq e$;
assume $v_2 \leftrightarrow \exists i. l \leq i \leq m - 1 \wedge a[i] = e$
 $rv := v_2$;
@post : $rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$

$G[a, l, u, e, rv]$ be the post condition. Then, the function call
return BinarySearch($a, m + 1, u, e$) translates to
assume $G[a, m + 1, u, e, v_1]; rv := v_1$;

Weakest Precondition

What is the precondition that must hold before the statement to ensure that the postcondition holds afterwards?

- $\{ ? \} x := x + 1 \{ x > 0 \}$
- $\{ ? \} y := 2 * y \{ y < 5 \}$
- $\{ ? \} x := x + y \{ y > x \}$
- $\{ ? \} \text{assume } a \leq 5 \{ a \leq 5 \}$
- $\{ ? \} \text{assume } a \leq b \{ a \leq 5 \}$

The weakest precondition is the most general one among valid preconditions. Weakest precondition transformer:

$$\text{wp} : \mathbf{FOL} \times \mathbf{stmts} \rightarrow \mathbf{FOL}$$

Weakest Precondition Transformer

Weakest precondition $\text{wp}(F, S)$ for statements S of basic paths:

- Assumption: What must hold before statement **assume** c is executed to ensure that F holds afterwards? If $c \rightarrow F$ holds before, then satisfying c guarantees that F holds afterwards:

$$\text{wp}(F, \text{assume } c) \Leftrightarrow c \rightarrow F.$$

- Assignment: What must hold before statement $v := e$ is executed to ensure that $F[v]$ holds afterward? If $F[e]$ holds before, then assigning e to v makes $F[v]$ holds afterward:

$$\text{wp}(F, v := e) \Leftrightarrow F[e]$$

- For a sequence of statements $S_1; \dots; S_n$,

$$\text{wp}(F, S_1; \dots; S_n) \Leftrightarrow \text{wp}(\text{wp}(F, S_n), S_1; \dots, S_{n-1}).$$

Verification Conditions

The verification condition of basic path

$$\begin{array}{c} @F \\ S_1; \\ \vdots \\ S_n; \\ @G \end{array}$$

is

$$F \rightarrow \text{wp}(G, S_1; \dots; S_n).$$

The verification condition is sometimes denoted by the Hoare triple

$$\{F\}S_1; \dots; S_n\{G\}.$$

Example

The VC of the basic path

$$\begin{aligned} @x \geq 0 \\ x := x + 1; \\ @x \geq 1 \end{aligned}$$

is

$$x \geq 0 \rightarrow \mathbf{wp}(x \geq 1, x := x + 1)$$

where

$$\mathbf{wp}(x \geq 1, x := x + 1) \iff x \geq 0$$

Example

Consider the basic path (2) in the LinearSearch example:

$$@L : F : l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$$

S_1 : assume $i \leq u$;

S_2 : assume $a[i] = e$;

S_3 : $rv := \text{true}$

$$@\text{post } G : rv \leftrightarrow \exists i. l \leq i \leq u \wedge a[i] = e$$

The VC is $F \rightarrow \text{wp}(G, S_1; S_2; S_3)$, so compute

$$\text{wp}(G, S_1; S_2; S_3)$$

$$\Leftrightarrow \text{wp}(\text{wp}(rv \leftrightarrow \exists j. l \leq j \leq u \wedge a[j] = e, rv := \text{true}), S_1; S_2)$$

$$\Leftrightarrow \text{wp}(\text{true} \leftrightarrow \exists j. l \leq j \leq u \wedge a[j] = e, S_1; S_2)$$

$$\Leftrightarrow \text{wp}(\exists j. l \leq j \leq u \wedge a[j] = e, S_1; S_2)$$

$$\Leftrightarrow \text{wp}(\text{wp}(\exists j. l \leq j \leq u \wedge a[j] = e, \text{assume } a[i] = e), S_1)$$

$$\Leftrightarrow \text{wp}(a[i] = e \rightarrow \exists j. l \leq j \leq u \wedge a[j] = e, S_1)$$

$$\Leftrightarrow \text{wp}(a[i] = e \rightarrow \exists j. l \leq j \leq u \wedge a[j] = e, \text{assume } i \leq u)$$

$$\Leftrightarrow i \leq u \rightarrow (a[i] = e \rightarrow \exists j. l \leq j \leq u \wedge a[j] = e)$$

$$\text{The VC is } l \leq i \wedge (\forall j. l \leq j < i \rightarrow a[j] \neq e)$$

$$\rightarrow (i \leq u \rightarrow (a[i] = e \rightarrow \exists j. l \leq j \leq u \wedge a[j] = e))$$

Partial Correctness

Theorem

If for every basic path

$\text{@} F$

$S_1;$

\vdots

$S_n;$

$\text{@} G$

of program P , the verification condition

$$\{F\}S_1; \dots; S_n\{G\}$$

is valid, then the program obeys its specification.

Summary

Inductive assertion method for proving partial correctness:

- ① Derive verification conditions (VCs) from a function.
- ② Check the validity of VCs by an SMT solver.
- ③ If all of VCs are valid, the function is partially correct.

The method can be automated, if proper loop invariants are given.

Automatically generating loop invariants, however, is not an easy task and remains an active research area.
